One of the most disturbing features of the failure of modern medicine, especially academic medicine, to face up to the implication of Freud's major discovery is the extraordinary ignorance one finds of what he actually thought and said There can be little excuse for ignorance of his life now that the brilliant and devoted biographical study by Ernest Jones—soon, I hope, to be completed—has appeared Were Freud's works not available in the happiest of English translations, one could excuse more readily ignorance of them , and I find it odd, for example, that few seem to have noticed that the fourteenth edition of the *Encyclopædia Britannica* (1929) contains a most precise article on psycho-analysis by Freud himself His account of the subject matter of psycho analysis is an extremely succinct and important one Now, over thirty years later, much could be said of the validity of the details of his exposition, but it is certain that in the history of medicine his name will live as long as that of any of the mighty originals we honour That the theory of psychology and the rigid system of treatment he built up are both unlikely to survive unaltered does not detract from his greatness, and, at this distance, they can be seen as the inevitable effects of the cultural atmosphere of the times and places in which he spent his formative years

* * *

Prejudice and bias aside, two important kinds of difficulty prevent easy recognition of the effects of emotion on the tissues On the one hand, the causative disturbance may be unrecognisable except by the trained observer, or, though less subtle, may still be beneath consciousness , or on the other hand there may be no symptoms to attract the patient's notice Between these difficulties come those disorders which, though apparent enough, do not make the patient think of an emotional origin—simply because the time relationship is not impressed on him either by previous experience or by immediacy of effect

I have said elsewhere (1953b) that for most people the state of health is not a very conscious matter unless sharp deviations from the customary state take place, and many will fail to recognise those differences of personality which to others are their distinguishing marks To feel well in the conventional sense is an exaggeration , when well one feels nothing of one's health unless in response to external stimulus In many circumstances, quite gross changes of mental comfort can occur without the patient considering even the possibility that his reaction has been other than ordinary If long experience has brought home to him that his usual response to worry or upset has been, say, abdominal discomfort, diarrhœa, frequency of micturition, or headache, then an unusual severity of such symptoms may make him aware that a particularly severe stress has been responsible, but even so apparently simple a correlation is by no means usual—and in the definition of stress it is prudent to remember Plutarch's remark that it is "man's nature to resent evil words more than evil deeds, for it is more easy to submit to injury than insult"—and in considering response to stress, to recall Shakespeare's famous lines "Give sorrow words, the grief that does not speak whispers the o'er fraught heart, and bids it break."

* * *

An almost insuperable difficulty arises where a response is bizarre, and I shall illustrate this by a few words on multiple lipomatosis. The ætiology of this curious disorder has been little discussed, though Heilmann and Sonneck (1953), describing a case in which the lipomatosis seemed to follow electric shock, refer to others attributed to head injury, particularly injury to the base of the skull.

When I first saw the condition twenty-five years ago, even the patient's subsequent suicide did not make me reflect on why he had developed an enormous number of lipomata. Early in the war, I saw a second patient who in six weeks had developed numerous lipomata about the arms, thighs, and trunk. There were so many large ones in the forearms that, when he presented arms, a tourniquet effect made him relax his grip quite quickly, and on two such occasions his rifle clattered to the ground. He presented an antecedent intense anxiety state based on readily understandable factors, and when we had relieved his emotional disorder he reminded us that no further lipomata had appeared, but again I thought little of the matter. On returning to civil life, I was almost at once presented with a third problem of this kind—the combination of an intense exhaustion and anxiety state in an exceedingly active and responsible young man with gross lipomatosis of acute onset, mainly affecting the arms. Twenty-nine lipomata were neatly excised while he was having a short course of modified prolonged narcosis, and I was greatly intrigued to find that, with the relief of his psychogenic disorder, no further lipomata appeared. I waited with some eagerness for another comparable patient, and within the last fortnight I have seen one. Unfortunately it is some seven years since his lipomata appeared, so that critical study of the life situation at the relevant time will be difficult, but it is clear that in this instance a man of 63 developed the condition in circumstances which caused him soon afterwards to retire prematurely from his occupation. Tentative exploration of the last patient has not gone further, but I would suggest that this slight personal experience of four patients with multiple lipomatosis cannot be dismissed as irrelevant to my main theme. I would agree at once that the development of benign fatty tumours seems a very odd way for the body to express its discontent, but if these observations have substance, then I would suggest that there is no tissue in the body which may not react in a similar way.

The effect of stress on body resistance to infection is difficult to define, although one suspects some close connection when one encounters, for example, a patient who has had pneumonia several times in thirty years, always immediately after severe stresses. *Recurrent* herpes simplex and zoster, in my small experience, has always been so correlated, and this view is shared by others (Weichselbaum 1936). When one feels that a real improvement has taken place in a patient's personal adjustment to life it is intriguing to hear comments such as "*It's odd I haven't had another attack, because, if this had happened to me before treatment I'm certain I* would have had a very bad attack—I suppose it's because I had begun to feel happier and easier." This remark was made by an intelligent patient who had failed to show her expected somatic reaction when her daughter was killed tragically the day after what was to have been a final discussion of her health.

There are those who insist that patients with disseminated sclerosis are apt to show a uniform type of personality. My co-editor, Hugh Garland, for example, writes:

> " . . . early examples of disseminated sclerosis, when there can be little possibility of personality changes having arisen through gross disease of the brain, show many striking features. Usually physically attractive, these people are almost invariably polite, quiet, pleasant and devoid of aggressive talk or behaviour; they dislike quarrels or arguments, or any show or display of temper. In the author's view it is this type of person, and probably only this type, which develops disseminated sclerosis, and in such people it is very commonly the fact that prior to the onset of the first symptoms, there has been clear evidence of emotional stress. It may well be that trauma, parturition and the other factors mentioned above operate by some similar mechanism." (Garland 1953.)

When one considers the difference in the possibility of regeneration in damaged nervous tissue as compared with tissues where normally mitosis is active and replacement constant and frequent (Leblond and Walker 1956), it seems clear that, if stress damage arises in the nervous system, the only recovery to be expected is the removal of the effects of immediate neuroglial or similar reaction. Schwab and Prichard (1950) studying a hundred parkinsonian patients with special interest in psychosomatic effects in stable, vulnerable, and difficult personalities concluded that there is a close correlation between personality and the effects of environmental stress. They found that, while all patients were temporarily worse with short-lived stress, only 12% of the 42 patients in the stable group showed permanent aggravation of their disorder when exposed to long-continued or severe stress, whereas 33 (27%) of the vulnerable and 25 (56%) of the difficult personality groups were so affected. Others have suggested that some patients with parkinsonism may be showing reaction to stress in the very centre of the integrating mechanism, and many examples of chronological correlation between exacerbations and stress are on record. Again, I had never considered this possibility until quite recently when I was a little chagrined by a patient's unprompted and quite categorical account of her correlation, not only of an exacerbation in the parkinsonism but also of its origin with clear cut episodes of severe stress.

The more one studies such matters, the more one realises how extraordinarily blind our preconceptions make us. We tend to see only what we expect to see, and it is hardly surprising that many can practice over a long period of years without ever realising that mental factors can induce a physical disease. Particularly is this understandable when one considers how very much more careful and understanding an approach is required to elicit this type of history. We may recall what Oliver Wendell Holmes said in 1883 about the futility of much of medical practice:

> " . . . many a suicide would have been prevented if the doctor's wife had visited the victim the day before it happened. She would have seen in the merchant's face his impending bankruptcy while her stupid husband was prescribing for his dyspepsia and indorsing his note. *She would recognize* the love lorn maiden by an ill adjusted ribbon—a line in the features—a droop in the attitude, a tone in the voice—which mean nothing to him, and so the brook must be dragged tomorrow." •

It cannot be said too often that when one is studying the possibilities of psychosomatic ætiology, to ask a patient whether anything may be worrying him is a waste of

time To ask whether he considers himself a worrier, or whether his family so judge him, will usually produce a relevant and unemotional response To ask how worry or upset affects him will similarly produce some useful information, although often thought and inquiry from relatives will be needed before even this question can be answered with even partial accuracy, but letting the patient talk and go on talking is the method of choice The hostility induced by Freud's emphasis on sexual aspects of psychogenesis has left a legacy of half-acceptance of his main principles, interpreted in a way that allows only the bizarre and exceptional circumstance to be effective in ætiology, whereas in general the everyday ordinary unsettled difficulties of personal inter-relationships are far more important

* * *

Attempting to determine the relationship of specific attitudes and emotions to bodily disease, Grace and Graham (1952) tried to define situations chronologically associated with symptoms, and obtain a description of the patient's attitude at the time They emphasised the necessity of getting from the patient a clear unambiguous statement of what he felt had happened to him and what he wanted to do about it *at the time of the occurrence of the symptom* They said that in their series "all patients with the same symptom complex described their attitudes towards the situation which precipitated it in essentially the same way" In urticaria, for example, the patients saw themselves as mistreated, either in words or deeds, and were preoccupied with what was happening rather than thinking of retaliation or of solving their problem In eczema, the feeling was of being interfered with or prevented from doing something, together with inability to think of a method of dealing with frustration the preoccupation being with interference and the people or situations frustrating the patient This contrasts with the preoccupation of the person with migraine, who strives to carry out a planned programme or reach some clear objective, the headache occurring with cessation of effort and being unrelated to success or failure here the typical statements quoted were "*I had to get it done,*" "*I had to meet a deadline,*" "I had a million things to do before lunch," "I was trying to get all these things accomplished"

Grace and Graham propose that emotion be defined as an attitude with its associated physiological changes Such generalisations—and there are many comparable ideas—are in my view still unjustified, but each seems to have its significant element of truth and value

* * *

Though many doctors and patients are quite unaware of psychosomatic relationships, some patients have intuitive awareness of quite surprising precision

> The husband of a patient whom I had known for a long time was telling me of his wife's eventual death, and, speaking of his adjustment to circumstances, remarked that he himself had had far less urticaria and paroxysmal tachycardia in the past year He was not my patient, and I had known nothing *of these disabilities*, *but a casual inquiry* produced the striking answer that he knew that his urticaria was an invariable response to grief, and, so far as he had determined, to no other circumstance, while the paroxysmal tachycardia was always produced by anger and by nothing else

The individual's pattern of reaction to a given emotion may well be constant for a short or long period, but in another patient the same reaction may be caused by quite a different circumstance This view is well illustrated by some recent experience with patients with psoriasis

I do not myself practice, and know only too little of, dermatology, but for some time I have had the habit of asking a patient who happens to have psoriasis, always at the end of a consultation—whether he has any views about its cause Four consecutive patients have attributed exacerbations of their psoriasis to emotional stress The first had found a feeling of injustice would be responsible within twelve to twenty four hours for fresh lesions, the second found her skin react to upset about illness in others within twenty four hours, a third correlated it precisely with pleasurable marital sexual experiences, while the fourth had discovered that pleasurable planning of business activity, while awake at night, was similarly responsible I have described these patients in a little more detail recently and also enlarged on the theme of how to get the information from the patient (Phillips 1956)

A delightful and significant experiment, entitled The Patient Sits Down, is described by White (1953) who, in a cardiological practice, noted how patients seated themselves in his consulting room He distinguished between patients who promptly sat down and leaned back in the chair, and those who sat on the edge of the chair, drew the chair close to the desk, and then sat down on the edge of the chair, or who drew the chair close to the desk, sat down on the edge of the chair, leaned forward, and rested the elbows on the desk He then studied whether removing the desk, so that no physical barrier existed between him and the patient, would have any effect on their seating habits He made the interesting observation that over 50% of patients sat at ease when there was no desk, in contrast with about 10%, when a desk was present Subsequent inquiries from individual patients suggested that this apparently trivial procedure produced not only a feeling of increased ease but also increased recollection of details previously forgotten about illnesses

It is difficult in a busy day to avoid the temptation to cut a patient short and to arrive at an opinion on too short a history and an adequate physical examination My experience is that one can seldom obtain even a sketchy view of the patient as a whole if less than forty minutes is taken over the history, and I am therefore shocked when I hear that there are already too many doctors My view would be that standards of medical practice will deteriorate progressively unless doctors have enough time to consider patients as individuals The implication is that more doctors are required, and that they should each be responsible for a smaller number of patients The total cost of a health service might well be little affected by such a change, for when public and profession had become reorientated in therapeutics, it might save much useless drug therapy and needless absence from work

* * *

I define psychiatric competence as the *ability* to relieve a child's enuresis by discussing with the child's parents—without seeing the child and best without discussing enuresis—their conflicts in important spheres of adjustment To some this definition will appear little short of outrageous I believe that careful examination of the definition leads to important principles in therapeutics I do not expect that doctors will quickly achieve such competence unless their interest be unusual, *but* I do suggest that many, five minutes after a consultation has started, have said to themselves "*only child*" Some no doubt will have gone further, simply because they have become aware, in some way, difficult to define, that a certain sort of person, is talking to them and have allowed a thought to flit through their minds, although the patient has talked only about his palpitation and chest pain, "I wonder has he an enuretic *child*"—and been right!

Present day trends in search for methods of relieving emotional tension and its effects are in certain well defined directions Firstly, and least used, is formal psycho analysis Next come short methods of psycho

therapy, consisting usually in more superficial studies of underlying tensions and perhaps little more than establishment of chronological correlation between stress and effect This is probably the commonest kind of approach Then come methods entirely mechanistic in concept, derived from experimental psychology, popular in limited informed circles and enthusiastically advocated by many completely ignorant of psycho pathology Next come methods which rely entirely on drugs which have either a general sedative effect or for which some special local effect within the nervous system is claimed—a method, of course, often used with another more fundamental approach Then come the very important neurosurgical approaches And finally the possibilities of group therapy appear to be of increasingly wide applicability and effectiveness

In assessing the place and relative values of these different ways of treatment, great difficulties arise at once The formal analysts tell us nothing of their failures and little enough of their successes Their method, as it would seem at present to be defined, makes it impossible that any analyst can treat in a working life time more than an insignificant number of patients Since treatment is recommended to last some five years, and during this period should occupy an hour a day for five or six days each week, any correlation between result and method must be extremely difficult to determine The analysts appear to forget that they are not treating patients in a vacuum All the ordinary impacts of life, all man's normal tendencies to try to do something about his own situation for himself, and all the influences of casual conversation, of reading, or of the psychotherapeutic effect of music and the arts, of worldly success or of emotional contentment, are by no means completely kept away from a patient because he is being psycho analysed Even had I the knowledge so to do, I could not here discuss the place or methods of psycho analysis, and I shall merely say that I agree entirely with Ida McAlpine's (1956) assessment in her Tribute to Freud, emphasising nevertheless a conviction that as a research method it has important and possibly unique contributions to make But clearly, from a practical standpoint, conditions as common as those we are considering can never be routinely treated by classical analysis The conditioning and comparable methods derived from pure psychology seem to me, even if successful in removing symptoms, to be symptomatic therapy, and general objections to exclusively symptomatic treatment apply forcibly to most of these mechanistic methods One feels they are little removed from treatment of the Charcot type of hysterical manifestation by crude suggestion—often enough immediately successful in relieving, for example, a hysterical paralysis, but failing to prevent later continued illness or calamities such as suicide Drug treatment is often a necessary adjuvant, but as a sole method it is in general very disappointing, as a sober recent review by Leiberman and Vaughan (1956) indicates Neuro surgical relief has been of enormous benefit to thousands of patients, but so far, at any rate, it has in the main been used far more in psychotic illnesses and very severe obsessional states, while in psychosomatic problems little experience has been gained

The fields in which group psychotherapy has been used extensively now include many common problems ranging between examples coming squarely into the definition of preventive action and those equally evidently in the domain of curative medicine Slavson (1956), speaking from a wide experience states that it was met with "singular receptivity not only from professionally trained persons or patients but from the general community as well Group psychotherapy uniformly evoked favourable response and unresistive acceptance from the intelligent men in the street, from newspapers, popular magazines and other media of communication, giving testimony to its acceptability" He goes on to say

> "It has been my conviction for many years that while the intelligence of masses cannot be trusted, their intuitive and instinctive responses are unfailing Aggregates weaken the ego and rational understanding but sharpen instincts the term 'group' has always held a special fascination for man partly because his survival in nature was conditioned by association in group life and partly because group living presented the individual with special and arduous difficulties Thus, all appeals to group action in group association command *ipso facto* attention"

You will not need to be reminded of Trotter's celebrated essay (Trotter 1916)

I have only once had the opportunity of examining some thousands of patients referred to me as an anonymous office-holder with unknown predilections and interests, and perhaps only the first thousand of these came fully into this definition At the Military Hospital, York, at the time of Dunkirk, I made a careful analysis of the first thousand patients referred to me, all with "organic" labels Of these I found that 30% had no trace of organic defect and had disabilities which were entirely functional, 40% had some organic signs but had a disability which was wholly functional, while 30% could receive an "organic" label—including, however, in this group peptic ulcer, asthma, and numerous other conditions which, I need hardly say, I placed in the "organic" category with considerable cynicism This "organic" group included 9 patients with post-encephalitic parkinsonism, 6 of whom—the only 6 correctly diagnosed—had been referred to me by a psychiatric colleague recently translated to an academic sphere!

If, as this and many comparable experiences, suggest, more than a third of all human illness contains an emotional element important enough to need recognition in treatment, it may be that the method of group therapy will prove the most practical means of extending psychotherapy on a sufficiently broad scale In contrast with the basic therapeutic principle in individual psychotherapy—the fresh exposure of the patient under more favourable circumstances to emotional situations formerly incompetently handled—in group therapy the environment is more variable, its effect on the patient more intricate, and the therapist's control on environmental factors less complete The simplest group treatment is the explanatory lecture in which the causation and mechanism of symptoms is explained To the friendless and isolated, preoccupied with troubles, it often brings considerable relief to realise in a group setting that many others have to contend with similar disabilities

One of the extraordinary things about group experience is the sharp reminder the therapist receives that words mean different things to different sorts of people, since untutored members of a group will quickly identify with astonishing precision the significance of quite ordinary remarks in group discussion, often to the initial discomfiture of a worker who may have spent hours in individual psychotherapy and missed the significance, in this way group therapy is an important educative method for the therapist The group is a testing place for social reality, for the patients become aware of discrepancies between their fantasies and the feelings they evoke in their fellows So many patients report that they have improved not only in the relief of symptoms but also in social relationships outside the group, and so often does this happen in patients in whom other methods have failed after long trial, that in most important clinics group therapy seems at present to be an extremely interesting approach

An old and much respected friend, Dr Hugh Barber, recently wrote

> "To understand the personality or constitutional make up of our patients is more in the realm of an art It is learned

time To ask whether he considers himself a worrier, or whether his family so judge him, will usually produce a relevant and unemotional response To ask how worry or upset affects him will similarly produce some useful information, although often thought and inquiry from relatives will be needed before even this question can be answered with even partial accuracy, but letting the patient talk and go on talking is the method of choice The hostility induced by Freud's emphasis on sexual aspects of psychogenesis has left a legacy of half-acceptance of his main principles, interpreted in a way that allows only the bizarre and exceptional circumstance to be effective in ætiology, whereas in general the everyday ordinary unsettled difficulties of personal inter-relationships are far more important

The individual's pattern of reaction to a given emotion may well be constant for a short or long period, but in another patient the same reaction may be caused by quite a different circumstance This view is well illustrated by some recent experience with patients with psoriasis

I do not myself practice, and know only too little of, dermatology, but for some time I have had the habit of asking a patient who happens to have psoriasis, always at the end of a consultation—whether he has any views about its cause Four consecutive patients have attributed exacerbations of their psoriasis to emotional stress The first had found a feeling of injustice would be responsible within twelve to twenty four hours for fresh lesions, the second found her skin react to upset about illness in others within twenty four hours, a third correlated it precisely with pleasurable marital sexual experiences, while the fourth had discovered that pleasurable planning of business activity, while awake at night, was similarly responsible I have described these patients in a little more detail recently and also enlarged on the theme of how to get the information from the patient (Phillips 1956)

A delightful and significant experiment, entitled The Patient Sits Down, is described by White (1953) who, in a cardiological practice, noted how patients seated themselves in his consulting room He distinguished between patients who promptly sat down and leaned back in the chair, and those who sat on the edge of the chair, drew the chair close to the desk, and then sat down on the edge of the chair, or who drew the chair close to the desk, sat down on the edge of the chair, leaned forward, and rested the elbows on the desk He then studied whether removing the desk, so that no physical barrier existed between him and the patient, would have any effect on their seating habits He made the interesting observation that over 50% of patients sat at ease when there was no desk, in contrast with about 10%, when a desk was present Subsequent inquiries from individual patients suggested that this apparently trivial procedure produced not only a feeling of increased ease but also increased recollection of details previously forgotten about illnesses

It is difficult in a busy day to avoid the temptation to cut a patient short and to arrive at an opinion on too short a history and an adequate physical examination My experience is that one can seldom obtain even a sketchy view of the patient as a whole if less than forty minutes is taken over the history, and I am therefore shocked when I hear that there are already too many doctors My view would be that standards of medical practice will deteriorate progressively unless doctors have enough time to consider patients as individuals The implication is that more doctors are required, and that they should each be responsible for a smaller number of patients The total cost of a health service might well be little affected by such a change, for when public and profession had become reorientated in therapeutics, it might save much useless drug therapy and needless absence from work

* * *

I define psychiatric competence as the ability to relieve a child's enuresis by discussing with the child's parents—without seeing the child and best without discussing enuresis—their conflicts in important spheres of adjustment To some this definition will appear little short of outrageous I believe that careful examination of the definition leads to important principles in therapeutics I do not expect that doctors will quickly achieve such competence unless their interest be unusual, but I do suggest that many, five minutes after a consultation has started, have said to themselves "only child" Some no doubt will have gone further, simply because they have become aware, in some way, difficult to define, that a certain sort of person, is talking to them and have allowed a thought to flit through their minds, although the patient has talked only about his palpitation and chest pain, "I wonder has he an enuretic child"—and been right!

Present day trends in search for methods of relieving emotional tension and its effects are in certain well defined directions Firstly, and least used, is formal psycho analysis Next come short methods of psycho

therapy, consisting usually in more superficial studies of underlying tensions and perhaps little more than establishment of chronological correlation between stress and effect This is probably the commonest kind of approach Then come methods entirely mechanistic in concept, derived from experimental psychology, popular in limited informed circles and enthusiastically advocated by many completely ignorant of psychopathology Next come methods which rely entirely on drugs which have either a general sedative effect or for which some special local effect within the nervous system is claimed—a method, of course, often used with another more fundamental approach Then come the very important neurosurgical approaches And finally the possibilities of group therapy appear to be of increasingly wide applicability and effectiveness

In assessing the place and relative values of these different ways of treatment, great difficulties arise at once The formal analysts tell us nothing of their failures and little enough of their successes Their method, as it would seem at present to be defined, makes it impossible that any analyst can treat in a working lifetime more than an insignificant number of patients Since treatment is recommended to last some five years, and during this period should occupy an hour a day for five or six days each week, any correlation between result and method must be extremely difficult to determine The analysts appear to forget that they are not treating patients in a vacuum All the ordinary impacts of life, all man's normal tendencies to try to do something about his own situation for himself, and all the influences of casual conversation, of reading, or of the psychotherapeutic effect of music and the arts, of worldly success or of emotional contentment, are by no means completely kept away from a patient because he is being psycho analysed Even had I the knowledge so to do, I could not here discuss the place or methods of psycho analysis, and I shall merely say that I agree entirely with Ida McAlpine's (1956) assessment in her Tribute to Freud, emphasising nevertheless a conviction that as a research method it has important and possibly unique contributions to make But clearly, from a practical standpoint, conditions as common as those we are considering can never be routinely treated by classical analysis The conditioning and comparable methods derived from pure psychology seem to me, even if successful in removing symptoms, to be symptomatic therapy, and general objections to exclusively symptomatic treatment apply forcibly to most of these mechanistic methods One feels they are little removed from treatment of the Charcot type of hysterical manifestation by crude suggestion—often enough immediately successful in relieving, for example, a hysterical paralysis, but failing to prevent later continued illness or calamities such as suicide Drug treatment is often a necessary adjuvant, but as a sole method it is in general very disappointing, as a sober recent review by Leiberman and Vaughan (1956) indicates Neurosurgical relief has been of enormous benefit to thousands of patients, but so far, at any rate, it has in the main been used far more in psychotic illnesses and very severe obsessional states, while in psychosomatic problems little experience has been gained

The fields in which group psychotherapy has been used extensively now include many common problems ranging between examples coming squarely into the definition of preventive action and those equally evidently in the domain of curative medicine Slavson (1956), speaking from a wide experience, states that it was met with "singular receptivity not only from professionally trained persons or patients but from the general community as well Group psychotherapy uniformly evoked favourable response and unresistive acceptance from the intelligent men in the street, from newspapers, popular magazines and other media of communication, giving testimony to its acceptability" He goes on to say

> "It has been my conviction for many years that while the intelligence of masses cannot be trusted, their intuitive and instinctive responses are unfailing Aggregates weaken the ego and rational understanding but sharpen instincts . the term 'group' has always held a special fascination for man partly because his survival in nature was conditioned by association in group life and partly because group living presented the individual with special and arduous difficulties Thus, all appeals to group action in group association command *ipso facto* attention"

You will not need to be reminded of Trotter's celebrated essay (Trotter 1916)

I have only once had the opportunity of examining some thousands of patients referred to me as an anonymous office-holder with unknown predilections and interests, and perhaps only the first thousand of these came fully into this definition At the Military Hospital, York, at the time of Dunkirk, I made a careful analysis of the first thousand patients referred to me, all with "organic" labels Of these I found that 30% had no trace of organic defect and had disabilities which were entirely functional, 40% had some organic signs but had a disability which was wholly functional, while 30% could receive an "organic" label—including, however, in this group peptic ulcer, asthma, and numerous other conditions which, I need hardly say, I placed in the "organic" category with considerable cynicism This "organic" group included 9 patients with post encephalitic parkinsonism, 6 of whom—the only 6 correctly diagnosed—had been referred to me by a psychiatric colleague recently translated to an academic sphere!

If, as this and many comparable experiences, suggest, more than a third of all human illness contains an emotional element important enough to need recognition in treatment, it may be that the method of group therapy will prove the most practical means of extending psychotherapy on a sufficiently broad scale In contrast with the basic therapeutic principle in individual psychotherapy—the fresh exposure of the patient under more favourable circumstances to emotional situations formerly incompetently handled—in group therapy the environment is more variable, its effect on the patient more intricate, and the therapist's control on environmental factors less complete The simplest group treatment is the explanatory lecture in which the causation and mechanism of symptoms is explained To the friendless and isolated, preoccupied with troubles, it often brings considerable relief to realise in a group setting that many others have to contend with similar disabilities

One of the extraordinary things about group experience is the sharp reminder the therapist receives that words mean different things to different sorts of people, since untutored members of a group will quickly identify with astonishing precision the significance of quite ordinary remarks in group discussion, often to the initial discomfiture of a worker who may have spent hours in individual psychotherapy and missed the significance, in this way group therapy is an important educative method for the therapist The group is a testing-place for social reality, for the patients become aware of discrepancies between their fantasies and the feelings they evoke in their fellows So many patients report that they have improved not only in the relief of symptoms but also in social relationships outside the group, and so often does this happen in patients in whom other methods have failed after long trial, that in most important clinics group therapy seems at present to be an extremely interesting approach

An old and much respected friend, Dr Hugh Barber, recently wrote .

> "To understand the personality or constitutional make up of our patients is more in the realm of an art It is learned

by experience which begins with sympathy and understanding rather than with theory and preconceived ideas

"It may be unfortunate scientifically but in practice it is common sense which will help our patients if we study their personalities in thought rather than in words The time is not yet come, and possibly it never may, when the whole of medical practice is based on exact science" (Barber 1956)

He will not take it amiss, I feel certain, if I comment that this can be criticised in that knowledge of human constitution is already usefully formalised by the studies of W H Sheldon (1940, 1942) and his school, which, while by no means removing the art from the physician's appraisal, teaches the inexperienced methods of distinguishing differences between individuals The studies of Sheldon and his associates on human temperament and human physique afford a most important and suggestive group of studies in constitutional differences

Their original thesis was that if human beings could be described in terms of their most deep seated "similarities and differences, it might prove not impossible to differentiate between heredity and the effects of environment" In the study of temperament, they started with 650 alleged traits of temperament which they reduced finally to a short list of 60 traits which seemed to incorporate all the *ideas* in the 650 All could be defined in the sense of having an opposite, and the individual traits were expanded to a 7 point graphic rating scale An initial survey of 20 students studied analytically for a year and all observed repeatedly in social settings in the same period with notes made on informal occasions and in analytical sessions, afforded a pilot study for a full scale appraisal of personality variation in university students

They distinguished three main groups of temperament which they called viscerotonia, somatotonia, and cerebrotonia The emphasis in the first group seemed to be on the gut, in the second on muscle and activity, and in the third on concentration and attention The degree in which each element could be identified in individuals was assessed

I would place both this study of temperament and the study of physique almost as obligatory reading for the informed doctor

* * *

The years since 1906 have seen a bewildering advance in the understanding of the complexities of biochemistry As to the metabolic activity of the proteins of the brain, for example, Gaitonde and Richter (1956) say that the evidence

" leads to the conclusion that the proteins of the brain *in vivo* are in a state of rapid dynamic change The half life of the methionine bonds in the brain proteins of about fourteen days, implies a half life of less than one day for a whole protein molecule of 80,000 molecular weight containing 15 methionine units If similar considerations are applied to the bonds of the 20 other amino acids and to the labile bonds of the phospholipid units in the lipoproteins, it would appear that the half life of some at least of the lipoproteins, which are the main organic constituents of the brain, must be of the order of seconds rather than days This may be relevant to the problem of the engram, or the permanent trace that is left when nerve tissue is stimulated"

It is clear from this sort of work that it will be the enzyme chemists, those interested in the cell and its anatomy, physiology, and pathology, and ultimately the quantum biologists, who will discover the mechanism of memory, for submolecular events are at work It is extraordinary how often some hitherto ignored or unknown substance has come to assume striking biological importance Interaction between most of these and substances now long studied in the physiology of the pituitary gland and associated neural areas has been almost always shown to occur There seems to be almost a rule that there is the potentiality at least of central control over the most remote peripheral mechanisms, a circumstance perhaps most clearly shown by Verney's demonstration of osmoreceptors (1947) and by his work on the effects of emotion on urinary secretion (1946)

An example of a substance whose importance has been relatively recently and still only partially appreciated is 5 hydroxytryptamine, of particular interest to the cardiologist since for the first time a relatively simple substance appears to be responsible for a valve lesion The right sided cardiac lesions apparently produced by the high blood levels of circulating 5 H T released from gut or hepatic argentaffinomata are themselves of profound interest The nature of the endocardial response produced suggests intriguing possibilities, especially when one considers that chemically 5 H T is related to plant growth hormones, that it is found in platelets and in concentration in the centrencephalon, that it is also released with the clotting of blood, and that it may be responsible for the fatal vasoconstriction of pulmonary embolism, renal cortical necrosis, and important effects on circulatory hæmodynamics both generally and locally in renal and coronary circuits No sufficient explanation of the usual localisation of rheumatic valve damage to the left side of the heart and the relatively unusual involvement of the valves of the right chambers has ever been found, and such explanation should also show why it is that the right sided lesions occur only in patients in whom there is also severe left sided damage It now seems less odd to me that when I first heard before the war that Flanders Dunbar (1943) and her associates were contrasting, from the point of view of their personality and make up, patients with rheumatic heart disease with those suffering from a variety of other disorders The idea then partly incomprehensible and partly fantastic now seems a little less outrageous

All the substances so far known to have profound local influences are capable of influence as to their amount and production by central events, and speculations could be continued in many directions for it is clear, as Dale (1943), and Page and McCubbin (1956), indicate, that much more will be discovered about this highly significant chemical

* * *

In 1918 Freud wrote a paper, Should Psychoanalysis be Taught at the University? He considered and advocated the advisability from two points of view—that of psycho-analysis and that of the university My own university regards a chair of mental health as a most urgent requirement Pressure comes most strongly from those university teachers and members of governing bodies who have seen tragic consequences of medical ignorance of psychology and psychiatry and also have witnessed remarkable results from highly skilled psychiatry Putnam (1899) in his famous Shattuck lectures, entitled Not the Disease Only but also the Man, made the point that "the physician is an educator," and goes on

"We all hear of the triumphs of surgery, and every doctor feels a personal pride in spreading the news of them abroad but there are not so many who know that there are men, as yet few in number, but of equal genius, who with equal devotion and study have been searching for means to change little by little the trend of the forces that work in the mind and are thus silently laying the foundations of a new departure in therapeutics This is education of a high order but such studies as these must yield conclusions that the well trained doctor will find useful in his daily practice The doctor is most obviously an educator in dealing with the training of children To learn to do this sort of thing, to speak and comprehend the mental language of all sorts and conditions of men, is one of the many important tasks which the physician will in time learn to perform"

Putnam considered "a thorough preliminary course in psychology and philosophy far above a knowledge of botany or zoology, and following close on chemistry and physics, in the preparation for the work of the general practitioner"—and this fifty seven years ago In my view, a university without a chair of mental health fails to recognise the paramount importance of knowledge of this subject in the education of all who have to deal with people either in work, in the family, in schools or other experience Only one university, as far as I know (that of British Columbia), has a chair of psycho analysis, but it is noteworthy that the North American universities have the most lively regard for the importance of mental health and education, and Dame Olive Wheeler, who has spent recent vacations lecturing at a number of them on these topics, tells me that the interest and critical appreciation of her audiences are outstanding One looks forward to the time when all faculties and all teachers at every level of education will have a common meeting place in university departments of mental health staffed with people representing many approaches and disciplines, and not bound to rigid doctrinaire systems

* * *

Medicine has to consider itself in the social setting of its time and I would think no one is more aware than a doctor of the changes in every aspect of life in the past fifty years The rate of change has been such that the situation for the practising doctor has become truly frightening His is the only profession in almost universal direct contact with the general public, and any thinking doctor will be aware that, if he has been qualified five years and has not been reading regularly, he is distinctly out of date In my view, if he has been qualified ten years and has not read regularly, he is dangerously uninformed The situation of anyone who left medical school twenty years ago and is still working on the teaching he received as a student without postgraduate education from journals, books, or meetings, is, unless he be a very unusual man, almost medieval as far as important parts of medical practice are concerned The rate of change is increasing and if Sarnoff (1956), for example, is correct—and I see no reason to doubt the general validity of his suggestion—the next twenty years will see the events of the past fifty years completely eclipsed by such advances as the availability of nuclear and solar energy, automatic instantaneous translation of languages, television in world-wide interindividual communication, revolution in all forms of aerial transport, beneficent automation, vast arrays of new synthetic materials, new sources of food and new methods of expanding harvests, new forms of electronic light to remove perils of night driving and flying, wide extension of the use of computors in recording and accounting, improved weather forecasting and even climatic control, universal education, a revival in religion, outlawry of war, and an avalanche of improvements in preventive medicine and the probable extension of human life span to almost a century Few would assert that many of these items will seem imaginative in twenty years' time The forecast is, perhaps, a little more precise than some would allow, but Sir George Thomson's *Foreseeable Future* (1955) does not differ very materially from it I am glad to see that Thomson believes "the old ways of thought inherited from the Greeks and Hebrews and modified at the Renaissance will gradually change" For me it is a matter of amazement that intelligent people should still consider there has been the slightest proof for the thesis that a classical education trains the mind in some unique fashion

The task of the practising doctor is already frighteningly complex, but if emotional factors already clearly determined in many frequent and important chronic disorders are also found of causative or other significance in diseases now thought to be the archetypes of "organic," then indeed will clinical differentiation become a nightmare unless medical education has changed fundamentally its bias against systematic knowledge of the workings of the mind, its ignorance of the constitution of emotions, and its discreditable running away from reality

The rate of change in the world is such that the famous comment of the author of the *Instincts of the Herd in Peace and War*, who for so unhappy a reason must be much in mind at present, is especially apposite "Conservatism then is functional in a practical art, but let this fact remind us that in science it is necessarily meaningless and always and wholly harmful" I suggest that before one dismisses mental factors in the ætiology of disease as the irrelevant irresponsible vapourings of the uncritical, attention be given to studies such as those of Guetzkow (1951), Asch (1951, 1952, 1955), and Miller and Dollard (1941) on the effects of group and social pressure on opinions, for these are significant and disturbing and highly relevant in their implications In all these matters, the view expressed when the Duke of Edinburgh at his conference last July, emphasised the place of humility and respect in interpersonal relationships of all kinds, must surely stand the test of time

* * *

Medicine before long will be faced with a public demanding a drug or alternative treatment for every discomfort, in the literal sense of the word, which may occur in life People are preoccupied with ends and not means Anxiety about security in home, work, social status, and national security is reaching pathological proportions, and every change in industrial method or material, in forms of energy or even astronomical theory, produces fresh hysterical herd reactions—for most of science and scientific changes are incomprehensible to the masses, and equally frightening Are we as a profession in general clearer in our views on mental health and the treatment of mental illnesses than we were three hundred years before Sherrington's Silliman Lectures? In *Macbeth* Shakespeare's physician is seen to be a cautious doubting man preferring the evidence of his own senses to the reports of others, competent in case-recording—even forestalling *Alice Through the Looking Glass* ("the horror of that moment," the King said, "I shall never never forget" "Oh yes you will," the Queen said, "unless you make a memorandum of it"), aware that sleep-walking can be due to nervous disturbance from ordinary as well as from bizarre happenings, and very conscious of the risks of suicide At the same time, with many a modern doctor, he suggests it is either for the Church or for the patient to deal with the problems of mental health, and, in the last resort, how like he is to most of us who prefer someone else to deal with the problems of mental health in our patients

Where then do Sherrington and Freud come closest together—the one philosopher and poet, as well as in Fulton's words "the most profound student of the nervous system the world has yet known," and the other initially biologist and neurologist, the main architect of our beginning understanding of the mind? The final sentences of *Man on his Nature* seem to me relevant and most noble words .

> "Natural knowledge has not forgone emotion It has simply taken for itself new ground of emotion, under impulsion from and in sacrifice to that one of its 'values,' Truth Its view of the world and of itself is based upon the purview of what by its lights it can accept as true In that way much that is comfortable in other religions lapses If you will, man's situation is left bleaker One feature of that situation is that the human mind such as it is, is left the crown of mind to which human life in all its needs has direct access Compared with a situation where the human mind beset with its perplexities had higher mind and higher personality than itself to lean on and to seek counsel from, this other situation where it has no appeal and no resort for help beyond itself, has an element of tragedy and pathos Ours is a situation which transforms the human spirit's task, almost beyond recognition, to one of loftier responsibility It elevates that spirit to the position of protagonist of a virility and dignity which otherwise the human figure could not possess It raises the lowliest human being conjointly with the highest, Prometheus like, to a rank of obligation and pathos which neither Moses in his law giving nor Job in all his suffering could surpass We have, because human, an inalienable prerogative

of responsibility which we cannot devolve, no, not as once was thought, even upon the stars We can share it only with each other "

" boys and girls whose precociousness suggests that they are likely winners of scholarships, are taken as young as possible and crammed with specialist knowledge like geese The harmful effects of this system are twofold In the first place, the late developer is penalized If, as I believe, the evolution of man from his sub human ancestors has largely been achieved by progressive delay in development, prolongation of childhood and retardation of maturity, the premium which we place on precociousness works directly against the processes which have made man what he is and may make him into *Homo sapientior* It is certainly to the good that there should be provision for rewarding the precocious, but surely not to the point where scholarships will be awarded to babies if they can converse before they are two years old, From their performance when at school it is clear that neither Newton nor Darwin would have won scholarships on our existing system, and that is serious

" The second harmful result of precocious specialization is that general subjects are displaced from a boy's or girl's education, perhaps for ever The effect of this bears more heavily on science than on the humanities, because if a boy spends in dissecting the dogfish and frog the time when he might be acquiring a grounding in English by the most critical method, which is by means of latin prose, it will be increasingly difficult for him to go back afterwards and make up for what he missed On the other hand, the boy who has had a grounding in the humanities is in the fortunate position that he can at any time broaden himself by simply walking into a laboratory, if only he will In my experience that is the source of the best scientists of all Incidentally, this is my contribution to the problem of increasing the supply of scientists, for there is no need to wait until all the schools have science masters, and fully equipped laboratories, if the universities will make scientists of students with a good general education "—MR GAVIN DE BEER in the Rickman Godlee lecture for 1956 delivered at University College Hospital

RHEUMATOID ARTHRITIS WITH CHRONIC LEG ULCERATION

J H ALLISON
M B Lond, M R C P
REGISTRAR

F RAY BETTLEY
M D Lond, F R C P
PHYSICIAN FOR DISEASES OF THE SKIN

MIDDLESEX HOSPITAL, LONDON

A GROUP of six patients with unusually chronic ulceration of the leg associated with a rheumatoid type of arthritis is here described Reasons are given for regarding these as manifestations of disseminated lupus erythematosus

Case-reports

Case 1 —A housewife, then aged 28, began to develop rheumatoid arthritis in 1950, 2 months after an attack of salpingitis which had settled down after treatment with penicillin and sulphonamides In 1952 she had a rash on the upper part of the front of her chest, 3 weeks after starting gold therapy 3 weeks later, the rash having subsided, gold injections were re started and continued for 14 weeks, when they were discontinued owing to the reappearance of the rash This subsided within 2 weeks of stopping the injections In 1954 subcutaneous swellings began to appear on the backs of her elbows During the period March, 1954, to March, 1955, she received two courses of bee sting therapy applied to the skin overlying her affected joints In June, 1955, an ulcer began to develop on each ankle, and in February, 1956, she had dry pleurisy lasting a week

Examination —In April, 1956, she was underweight (6 st 10 lb) and crippled with rheumatoid arthritis, many subcutaneous "rheumatoid" nodules were present on the extensor surfaces of her arms and over her scapulæ There was a clean-based ulcer 7 5 × 5 5 cm on the outer side of her right ankle and one 3 × 2 5 cm on the outer side of the left ankle The finger nail folds showed many elongated telangiectases

Investigations —Urine deposit—a few red cells and white cells Culture sterile Blood urea 27 mg per 100 ml Urea clearance 50% and 31% of normal Intravenous pyelogram normal Blood counts showed persistent hypochromic anæmia White cell counts normal Blood for lupus erythematosus (L E) cells strongly positive Plasma proteins 7 8 g per 100 ml (albumin 3 5 g, globulin 4 3 g) Electrophoretic pattern raised γ globulin and α_2 globulin Blood Wassermann reaction negative

Progress —The smaller ulcer healed in 7 weeks with bed rest and local treatment The larger ulcer healed only after pinch grafting, but 12 weeks later it broke down and the whole graft was lost At the same time a fresh ulcer appeared just below the outer side of the left knee

Case 2 —A housewife, then aged 51, first developed symptoms of rheumatoid arthritis in 1943 From 1951 to 1954 she was treated with courses of phenylbutazone and gold In 1953 nodules appeared over her elbows, and early in 1955 an ulcer developed on her left ankle

Examination —In February, 1955, she was obese and crippled with rheumatoid arthritis, with "rheumatoid" nodules on the backs of the arms and hands An ulcer 10 × 6 cm was present on the outer side of the left ankle and one about 2 cm across on the medial side of the base of the left first toe X ray examination of the chest showed an area of segmental collapse at the right base which persisted in spite of active treatment In May and October she had two attacks of constant lower abdominal pain associated with nausea and vomiting, and a temperature of 101°F on one occasion, apart from slight tenderness, no other abnormal findings were made clinically or radiologically In August she had an attack of loss of consciousness lasting 2 minutes While lying in bed she became cyanosed but there was no clonic phase and she was not incontinent On recovery she complained of severe right sided headache Heart and central nervous system were subsequently normal, as were the electro encephalogram and skull X ray films

Investigations —Urine normal Blood counts showed constant hypochromic anæmia and leucopenia Blood for L E cells strongly positive on two occasions and negative on two A positive finding was not associated with any exacerbation of her condition Plasma proteins 7 7 g per

100 ml. (albumin 3·8 g., globulin 3·9 g.). Electrophoretic strip showed a raised α_2 globulin and a slightly raised γ globulin. Wassermann reaction negative.

Progress.—No healing at all could be induced in these ulcers in spite of 9 months in hospital. Grafting failed, as did local injections of hydrocortisone. Systemic steroid therapy was not given owing to her age, and the marked osteoporosis resulting from her immobility.

Case 3.—A man first developed symptoms of rheumatoid arthritis in 1947, at the age of 40. In 1949 he had dermatitis following two courses of gold injections. In the same year an ulcer developed on the outer side of his right ankle, and in 1954 on the medial side of his right first toe. Also in 1954 nodules appeared over his elbows. In June, 1955, he was found to have left-sided papillœdema and right-sided optic atrophy. At the time it was thought that this might be secondary to a toxic hydrocephalus, either in association with the arthritis, or due to phenylbutazone.

Examination.—In December, 1955, he had crippling rheumatoid arthritis, "rheumatoid" nodules over the elbows, and a clean based ulcer 5 × 6 cm. over the outer side of the right ankle and one about 1 cm. across over the medial side of the right first toe.

Investigations.—Urine normal. Persistent normochromic anæmia. White cells normal. Blood for L.E. cells positive. Plasma proteins 6·9 g. per 100 ml. (albumin 4·4 g., globulin 2·5 g.). Electrophoretic pattern showed a raised α_2 globulin. Wassermann reaction negative.

Progress.—No change in the appearance of the ulcers during 2 weeks in hospital.

Case 4.—A lorry driver developed symptoms of rheumatoid arthritis in 1946 at the age of 40. In 1952 nodules appeared over the elbows, and in October, 1955, an ulcer developed on the right lower leg. Previous treatment for the arthritis included gold, phenylbutazone, and corticotrophin (A.C.T.H.), with no recorded drug eruption.

Examination.—In December, 1956, he had gross arthritis with rheumatoid nodules and a clean-based ulcer 2·5 cm. in diameter over the medial side of his right lower leg. All tendon reflexes were brisk, with bilateral extensor plantar responses. There was superficial sensory loss over the dorsum of the left foot. Cerebrospinal fluid was normal. X-ray films of the cervical spine showed spondylosis, but those of the lumbar spine showed no abnormality. Dr. R. Gilliatt considered that the neurological findings were probably due to the patient's cervical spondylosis.

Investigations.—Persistent microscopic hæmaturia. Renal function tests and pyelogram normal. Cystoscopy by Mr. E. W. Riches showed hyperæmia of the prostatic urethra of sufficient degree to account for the hæmaturia. Blood count normal. Blood for L.E. cells negative on eight occasions. Plasma-proteins 6·1 g. per 100 ml. (albumin 3·4 g., globulin 2·7 g.). Electrophoretic pattern showed grossly raised α_2 globulin.

Progress.—There was no healing on bed rest and local applications alone. Healing began and continued slowly to completion over 12 weeks on daily corticotrophin (A.C.T.H.) gel intramuscularly.

Case 5.—A housewife first developed symptoms of rheumatoid arthritis at the age of 20 in 1934. She had gold dermatitis in 1935. A severe relapse of her arthritis followed pregnancy in 1943 and about the same time nodules began to appear on the backs of her hands and elbows. In 1953 an ulcer rapidly developed over her left ankle. The following year she developed soreness of the eyes and has since been under Mr. Derek Ainslie's care for the treatment of episcleritis and scleritis.

Examination.—In April 1954, she had very severe arthritis, "rheumatoid" nodules over the elbows and backs of hands and a clean based ulcer 10 × 9 cm. over the medial side of her left ankle.

Investigations over the years 1952 to 1956 have shown recurrent urinary infections. Pyelogram normal. Blood counts have shown a persistent normochromic anæmia. White cells normal. Blood for L.E. cells negative on the one occasion tested. Electrophoretic pattern showed raised α_2 globulin. Wassermann reaction negative.

Progress.—Two attempts at grafting in July and August, 1953 failed. No local treatment was of any avail. The ulcer eventually healed in March 1956 4 weeks after beginning oral cortisone. 2 weeks later, however, a fresh ulcer developed on the medial side of the left ankle. This ulcer was still present in September, 1956, in spite of continued oral cortisone (25 mg. b.d.).

Case 6.—This man, then aged 45, first developed symptoms of rheumatoid arthritis in 1945. In 1947 he had nodules over the left elbow for 6 months. At the time he was told that they were "rheumatoid." Raynaud's phenomena in the hands and feet began in 1952. In 1953 he had gold dermatitis and in April 1954, an ulcer appeared on the medial side of the right ankle.

Examination.—In November, 1954, he had severe arthritis, dusky erythema, and telangiectases at the bases of the finger-nails, and a clean based ulcer 2·5 cm. in diameter over the medial side of the right ankle.

Investigations.—Urine deposit: occasional red cells on admission; subsequent deposits normal. Blood counts showed mild hypochromic anæmia. Blood for L.E. cells (November, 1954) negative; (September, 1956) positive. Plasma-proteins 6·0 g. per 100 ml. (albumin 3·6 g., globulin 2·4 g.). Electrophoretic pattern showed a raised α_2 globulin.

Progress.—The ulcer slowly healed over 12 weeks' treatment in hospital, during which time he received hydrocortisone subcutaneously into the base of the ulcer (25 mg. twice weekly).

Histology of the Ulcers

Biopsies were made in cases 1, 2, 5, and 6. They may be considered together.

The histological features were best shown by the biopsy specimen from the edge of the deep ulcer in case 5. At the margin of the ulcer its floor was formed by inflammatory vascular granulation tissue, but this soon gave place to necrotic tissue which extended in places to the deep limits of the specimen, which was 0·75 cm. thick. Irregular band-like areas of necrosis of the fibro-fatty subcutaneous tissue and dermis extended some distance beneath the apparently intact skin, and the presence of necrotic tissue at the deep limit of removal of the specimen made it hardly surprising that grafts failed to take over the ulcer. The necrotic areas, though so extensive and involving fatty tissue in addition to collagen, had at their margins palisaded rows of elongated histiocytes characteristic of the nodules of rheumatoid arthritis. Necrotic fat cells were seen in places surrounded by histiocytes or foam cells, and a few giant cells were present. In the areas intervening between necrotic zones there was considerable fibroblastic proliferation and infiltration with lymphocytes and plasmacytes. Smaller biopsies from the ulcer floor of this patient at a later stage showed only non-specific chronic inflammatory changes with a granulation lining to the ulcer.

Small biopsies from the margin of the ulcerated area in cases 1, 2, and 6 showed necrotic collagen bounded by a palisade of histiocytes and fibroblasts together with occasional giant cells flooring the ulcer, but without any extensive necrosis in the deeper tissues.

Discussion

We have been struck by the similarity of the clinical pictures presented by these six patients. All had severe, crippling and apparently typical rheumatoid arthritis with many subcutaneous nodules; and the appearance of the ulcers was so uniform that, after seeing the first few patients, we felt that cases could be recognised by an examination of the ulcer alone.

In most cases the ulcers were on the lower third of the leg either on the inner or on the outer surface; in one case the upper part of the leg, just below the knee was involved and in another the toe and foot. We have not been able to witness the onset, but it seems that the earliest sign is a painful induration about 1 cm. across, which in the course of a week or two breaks down to form a punched out ulcer. In case 1 an ulcer 3 weeks old was already deeply punched out, about 1·5 cm. across, with smooth regular edges. There was no slough and the floor appeared to be formed by the subcutaneous tissue. Around the ulcer was a dark red flush extending about 3 cm, with very little palpable induration and no surrounding œdema Larger ulcers retain these characteristics The largest have been 10 cm across, always with smooth even outlines The floor is uneven, with a varying amount of whitish slough which can usually be easily removed, and comparatively little pus Granulations do not form readily Surrounding erythema and induration are not prominent, and subcutaneous œdema is slight or absent Pain is a constant feature, sometimes severe

Varicose veins, antecedent phlebitis, and other evidence of vascular stasis in the legs, were not found In only one of these patients did the ulcer heal with rest in bed and local treatment with antiseptics or antibiotics, and it seemed clear that neither local infection nor vascular stasis was playing an essential part The leg pulses and the skin-temperature were normal

Laine and Vainio (1955) reported twelve cases of skin ulceration among about two thousand patients with arthritis Their description of torpid ulcers resulting from breakdown of a cutaneous nodule fits in with our observations, but they do not seem to have been struck by any other features in their cases Skin ulceration is not a recognised feature of rheumatoid arthritis and in all our cases further investigation has yielded more information In four of the six, L E cells have been found in the peripheral blood, four have had drug eruptions in the past, a multitude of other symptoms of great variety were all compatible with the diagnosis of disseminated lupus erythematosus

The distinction between rheumatoid arthritis and disseminated lupus erythematosus is perhaps not so clear or so valid as terminology would imply, on the other hand, the diagnosis of disseminated lupus erythematosus covers a wide variety of clinical syndromes There is a great deal of difference between our cases and the more acute syndromes with skin eruptions, grave systemic upset, and a high mortality, even though the underlying pathological mechanism may be closely similar Harvey et al (1954), in a comprehensive review, do not include skin ulceration of this kind as a feature of disseminated lupus erythematosus All our patients had "rheumatoid arthritis" as their severe and dominating feature, all are running a chronic course, and only in case 2 has the general health been much affected This seems to indicate a relatively benign and slow progress of the disorder Our view that the skin ulceration is a part of the general illness is supported by its failure to improve with ordinary local treatment and by the recovery which followed steroid therapy in three patients

The mechanism of the ulceration is not certain Laine and Vainio suggest that the ulcers result from the breakdown of rheumatic nodules, but this does not seem to be so in our cases We did not find any notable induration in the base of the ulcers, and in no case had the patient been aware that a subcutaneous nodule of the usual type preceded the ulcer In case 2 several ordinary rheumatic nodules had broken down, discharging on the surface through a small slit-like sinus, and sufficed to emphasise the different picture thus produced Histological studies suggest that collagen necrosis may be the primary lesion, it may be of course that the primary lesion in the skin is the same as that which originates a rheumatic nodule in the deeper tissues, forming an ulcer in the one case and a proliferative tissue reaction in the other Our histological findings are compatible with this explanation, but evidently more biopsies, preferably of early lesions, are required It is noteworthy that all our patients had many subcutaneous nodules this is perhaps of significance since most series of rheumatoid arthritis give a frequency for nodules of no more than about 20% of cases

That we have observed six cases of this kind in the space of 2 years suggests that they are not extremely uncommon In view of their site it may well be that they are usually regarded as due to vascular stasis to which the immobility produced by arthritis contributes We believe, however, that though vascular stasis may play a minor part in producing the lesion, the distinction from ulceration due to stasis can be clearly drawn by the absence of all evidence of venous stasis and the failure, usually, of the ulcers to make any notable response to rest in bed The distinction is an important one, partly because of the disseminated character of the underlying disease, partly because of the entirely different treatment requirements Steroid therapy, which regularly produces a response in disseminated lupus erythematosus, is probably the only measure likely to help the ulcers

In three cases we were particularly struck by the failure of grafting These were all granulating satisfactorily and appeared to be ideally suitable, so that the failure of grafting was surprising It perhaps suggests that auto-antibodies may be responsible for the destruction of the graft, on the other hand, histological examination suggested that the grafts failed because an ulcer which appears to be granulating well still has necrotic collagen in its base

Summary

Six patients are described, in all of whom a rheumatoid type of arthritis was followed by painful ulceration of the leg Further observation permitted the diagnosis of disseminated lupus erythematosus

Owing to the multi faceted clinical picture shown by these cases, they have been seen by many members of the staff of the Middlesex Hospital Thanks are due to them for permission to extract details from their records and particularly to the staff of the Bland Sutton Institute of Pathology and the Courtauld Institute of Biochemistry for their work on the special investigations

Cases 1, 2, and 6 were shown at a meeting of the dermatological section of the Royal Society of Medicine on Oct 18, 1956

STEVENS-JOHNSON SYNDROME

A REPORT OF FIVE CASES AND A DISCUSSION ON ÆTIOLOGY AND TREATMENT

IAN A SHORT
M B Glasg, M R C P, F R F P S
SENIOR MEDICAL REGISTRAR, MANCHESTER ROYAL INFIRMARY

THOUGH much has been written about erythema multiforme exudativum (Stevens Johnson syndrome) the ætiology is still in doubt, and the efficacy of treatment is by no means established Five cases are here presented, four of which I saw in the medical wards of two hospitals, the fifth was not seen, but her records were found in reviewing cases of erythema multiforme in one of these hospitals They are reported for the following reasons

(1) Two cases were fatal—an uncommon outcome

(2) In one case necropsy and microscopic examination revealed changes not previously described

(3) The difficulties of ascribing this (or indeed any) condition to drug allergy are demonstrated

(4) The difficulties of ascribing curative properties to any drug, and the tendency to repeated self limited attacks with eventual complete remission, are illustrated

Case-reports

FIRST CASE

A motor driver and oil storeman aged 25 was admitted to hospital on Nov 24, 1949, complaining of pain in the left side of the chest and productive cough for 8 days He had been off work for 4 weeks because of a severe "chest cold"

This had apparently cleared up, and he had been up and about for a few days when he developed the pain in his chest, which was pleuritic Since then a troublesome cough had appeared, with copious pinkish sputum On the day before admission, the pain in the left chest was replaced by an aching pain across the front of the chest, not aggravated by deep breathing or coughing His nose had been blocked, and had bled several times He had no other symptoms His previous health had been good, he had never been given sulphonamide drugs, and there was no personal or family history of allergy His father had died of "nephritis and hypertension" and his sister had died in her thirties of "coronary thrombosis" unconfirmed by electrocardiogram or necropsy

Examination

His temperature was 100 8°F, pulse rate 86 per min, and respiration rate 25 per min on admission There were no rashes or palpably enlarged lymph-glands His nose was blocked and his voice nasal in character, his face appeared rather bloated A whitish membrane covered the tongue and fauces, and the tonsils were enlarged There was diminished movement at the left lung base and medium râles were heard at both bases

The blood pressure (B P) was 145/80 mm Hg No other abnormality was made out, and the urine was normal

Treatment and Progress

He was given crystalline penicillin 125,000 units 3 hourly intramuscularly, his temperature varied between 102°F and 98°F The nasal congestion increased until on Nov 28 the nose was blocked with blood clot, and the fauces, uvula, palate, and tongue were covered with raised yellowish white papules with surrounding œdema and erythema The chest signs were unchanged, and radiography had shown prominent hilar shadows and some loss of translucency in the right costophrenic sinus The white cell count was 6000 per c.mm with a normal differential count Bacteriological examination of the sputum and throat swabs revealed no specific pathogens Agglutination tests for the enteric group and brucella were all negative

The conjunctivæ became inflamed to the extent of chemosis The voice was reduced to a croak, and the breathing was stertorous Necrotic ulcers on the fauces became confluent, and shallow necrotic ulcers appeared over the buttocks and elbows These lesions began as vesicles, became hæmorrhagic, and then broke down to form ulcers with dry black bases, varying from $^{1}/_{8}$ to $1^{1}/_{2}$ in in diameter The fauces and uvula became so necrotic that the latter seemed on the point of sloughing off, and a few hæmorrhagic lesions appeared on the lips The conjunctivitis remained acute and subconjunctival hæmorrhages appeared Cultures of further throat swabs produced a growth of *Staphylococcus pyogenes*, and no diphtheria or Vincent's organisms were detected The blood was sterile and contained no cold agglutinins The white cell count rose to 12,000 per c.mm with a preponderance of polymorphs, and the hæmoglobin fell from 80 to 60% (Sahli) The erythrocyte sedimentation rate (E S.R) (Wintrobe) was 58 mm in one hour The blood Wassermann reaction was "? negative" and Meinicke "negative" As the illness progressed, a little albumin was found in the urine and a few granular casts There was slight œdema of the ankles and a left sided pleural effusion appeared Aureomycin (chlortetracycline) 250 mg orally 6 hourly was given from Dec 2 to Dec 5, and then promethazine 25 mg orally t i d The penicillin was continued and mouth washes given He died on Dec 9 after gradual weakening of respiration

Necropsy

There was congestion and ulceration of the entire respiratory tract The lungs, particularly the lower lobes, were studded with large yellowish necrotic zones which were firm and honeycombed Both lower lobes were covered with a fibrinous exudate The hilar lymph glands were fleshy, large, and hæmorrhagic

The heart was large (500 g) but, apart from mild atheroma in the coronary arteries, was normal A large ulcer (again with a yellowish tinge) was found in the jejunum, and there were many superficial ulcers in the ileum The liver was very large (3000 g) but appeared normal in texture The spleen was also large (700 g) and covered with a fibrinous exudate On section the whole spleen appeared to be in a state of infarction with numerous yellowish necrotic areas again with a honeycomb appearance The kidneys were a little larger than normal and the right contained a few recent infarcts

Histology

Lungs —The essential lesion in the lungs seems to be fibrinoid necrosis of the capillaries and complete destruction of lung tissue in the affected areas These areas are seen as foci of necrotic cellular debris with a surrounding granulomatous reaction with giant cells

Kidneys —In the right kidney there are typical segmental and focal lesions of polyarteritis nodosa involving the interlobular arteries, with infarction of the corresponding segments of parenchyma The glomeruli have the appearances of periglomerular granulomata described by Davson, Ball, and Platt (1948)

Spleen —In the spleen there are multiple and sometimes confluent necrotic foci of varying size with surrounding granulomatous reaction, as well as occasional segmental fibrinoid necrosis of trabecular arteries

Skin —The lesions of the skin and mucous membranes are essentially infarcts

Lesions of polyarteritis nodosa are confirmed microscopically in the testes, skeletal muscles, myocardium, and peripheral nerves

The pathological diagnosis is Wegener's granulomatosis A more detailed description of this case will be published in a journal of pathology.

SECOND CASE

An unmarried woman clerk aged 33 was admitted to hospital on June 19, 1950, with a history of joint pains for 10 days and scattered skin lesions for 7 days After 2 days of vague stiffness in the limbs, she had severe aching pains in the arms, and her hands and wrists began to swell, at the same time an eruption appeared on the buttocks The pain continued for 3 days and then improved She was then given salicylates by her doctor, and next day her pains were again severe and seemed to flit from joint to joint On admission she complained little of joint pain, however, but mainly of ulceration of the mouth which had appeared the previous day At the same time a rash had appeared on both hands and the right elbow, and below the left breast There had been no cough and no urinary upset, and menstruation was normal 6 months previously she had had an attack of joint pains and mouth ulceration lasting only a few days

At 18 she had had radiotherapy for thyrotoxicosis but the result was poor For 2 years before admission she had been taking thiouracil, never less than 50 mg daily, and for many months 75 mg Otherwise her health had been good and she had never taken sulphonamide drugs There was no personal or family history of allergy

Examination and Investigations

Her temperature was 101 4°F, pulse rate 120 per min, and respiration rate 27 per min on admission She was flushed and her eyes were prominent, but there was no conjunctivitis Enlarged lymph glands were noted in the retro auricular regions and in the posterior triangles of the neck The right lobe of the thyroid gland was enlarged and firm Scattered macules and vesicles were present over the scalp and forehead, and on the dorsa of the hands and wrists A few of the vesicles were hæmorrhagic, and under the left breast there was a weeping maculo papulo vesicular eruption There were a few hæmorrhagic vesicles over the right olecranon, and a further twenty over the sacrum and buttocks ($^{1}/_{4}$ in in diameter) The remaining areas of skin were flushed but otherwise normal

There was a hæmorrhagic vesicle on the lower lip, and sordes on the inner aspect of the lips The tongue was coated with a brownish fur, and ulcerated, most deeply at the right border The upper pole of the left tonsil bore a yellowish slough, and there were small ulcers over gums and fauces The joints seemed normal apart from some pain and tenderness in the knees and a doubtful effusion into the left knee Apart from the expected manifestations of thyrotoxicosis, the cardiovascular system was normal There was no evidence of pulmonary disease The external genitalia appeared normal The white cells numbered 3500 per c mm on admission and 50% were polymorphonuclear cells Platelets were present in normal abundance

Treatment and Progress

Penicillin 125,000 units 8 hourly was given from June 19 to 30 and promethazine, 25 mg t i d from June 19 to 26, and 25 mg daily till July 1 After 2 days her general condition had greatly improved, and after 5 days she was apyrexial

The condition of her mouth and skin improved steadily and the blood picture remained the same

Thyroidectomy was later performed by Mr T Murray Newton and although *3 months* had elapsed since thiouracil was stopped, the gland was still very vascular and showed the changes characteristic of thiouracil therapy *Her subsequent* health has been good

THIRD CASE

This patient was not seen by me but her records were found among those of cases of erythema multiforme admitted to the Western Infirmary, Glasgow

An unmarried girl of 23 *was* admitted from an island of the Outer Hebrides on Nov 12, 1941 She was then suffering from the *fourth* of a series of attacks—the first three having been *in* February, July, and September of the same year Each consisted of ulcerative stomatitis, conjunctivitis, vesicular and pustular lesions on the trunk and limbs, and an apparently *severe anæmia*

Evidently she was severely ill each time Her own doctor was very anxious about her and suspected agranulocytosis In the absence of local *facilities*, in war time, he was forced *to* risk *giving her* sulphonamides, and the results appeared *good Eventually* she was referred to hospital because it *was feared that* a further attack might prove fatal She had had a child a year previously, and the puerperium was complicated by a "somewhat toxic spell" Her doctor could not be sure whether he gave her sulphonamides at that time but thought he might well have done so

She spent only 3 days in hospital and the notes are not very full Her hæmoglobin was 55% (Sahli) but there is no record of further blood examinations A chest radiograph and a *fractional gastric* analysis were normal

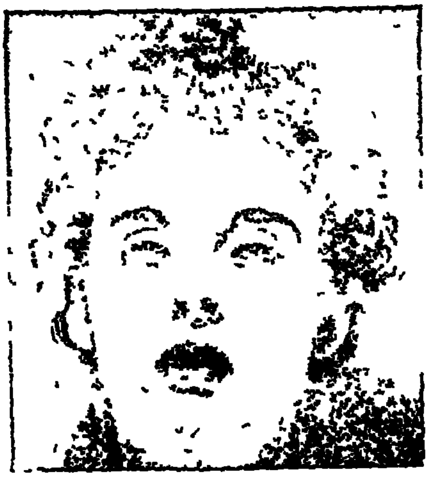
In 1951 her doctor was able to tell me that she had had one further *attack* and had thereafter remained well There was no allergic background, but her half sister had a mild erythema multiforme, *followed* by pulmonary tuberculosis from which she died

FOURTH CASE

A shop manageress aged 23 was admitted to hospital on *Dec 23, 1953* A week before, malaise, sore throat, headache, and cough had developed She had sweated unduly and her voice had become hoarse 4 days before admission her eyes became painful and inflamed, and her mouth and lips became swollen and ulcerated On the night before admission she was delirious There was no history of dysuria or of urethral or vaginal discharge She had had sulphonamides for 3 days and two *injections of* penicillin Her previous health had been good

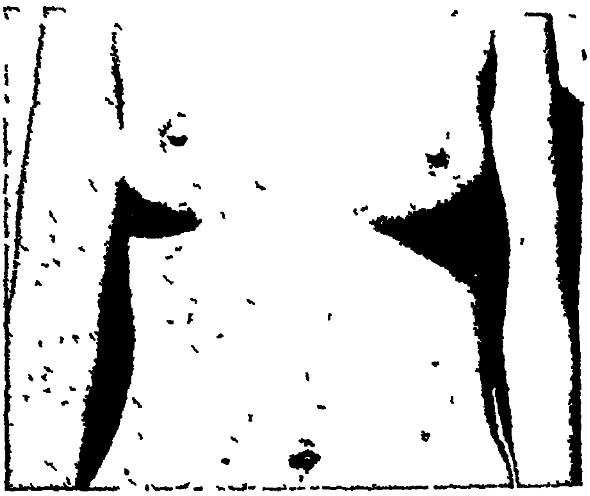
Examination

Her temperature was 100 6°F and she looked *ill* There was ulcerative stomatitis and hæmorrhagic crusting of the lips and buccal *mucosa* The conjunctivæ were much injected and œdematous No enlarged lymph glands were found Her limbs and trunk were covered with scattered erythematous circular lesions up to 1 cm in diameter These are *shown in the figure Some were of the* "*iris*" *type No* abnormality was made out in the chest on admission, but 3 days later clinical and radiological signs of left basal collapse and consolidation appeared The skin lesions did not ulcerate, but several became bullous Her mouth was very uncomfortable, and eating and speaking caused pain



Treatment and Progress

On the day after admission the temperature returned to normal, and in the next week reached 99°F only twice A course of cortisone by intramuscular injection was begun on Dec 24—100 mg t i d for 1 *day, 100 mg b d* for 2 days, and then 100 mg daily During this period the skin lesions persisted but there was some improvement in the conjunctivitis The mouth remained grossly ulcerated



Skin lesions in case 4

On Dec 29 the temperature rose suddenly to 103°F and corticotrophin (A C T H), 25 mg t i d intramuscularly, was substituted for cortisone 4 days later she was very much better The mouth was almost healed and the skin lesions were fading The eyes were almost back to normal Corticotrophin gel was then given (20 mg daily for 15 days) and there was no recurrence of symptoms She was also given crystalline penicillin, 500,000 units intramuscularly on Dec 29, followed by procaine penicillin 300,000 units b d *for 5 days*

The white cell count on admission was 7400 per c mm *with a normal* differential count On Dec 29 this had risen *to* 13,000 per c mm The E S R (Wintrobe) was 4 mm in *one hour on Dec 29* Blood culture was sterile and two *buccal swabs showed no* specific flora on direct examination and *culture* A repeat chest radiograph on Jan 7, 1954, showed *that* the basal shadow on the left side had disappeared

FIFTH CASE

A woman aged 18 was admitted *to hospital on* April 17, 1954 She had been married in February, 1954 Cystitis had *troubled* her for 5 weeks before admission From April 3 *to 7 she had* had a course of sulphadimidine On April 14 she began to complain of sore throat, painful eyes, and a rash, and on April 15 a course of chloramphenicol was begun

Examination

On admission she was very ill and semicomatose The temperature was 101°F and there were signs suggesting *bilateral* bronchopneumonia *There was a generalised* macular rash with bullæ, and gross ulceration of the mouth and fauces She had chemosis and purulent conjunctivitis There were no vulvar lesions She was put in an oxygen tent and given *aureomycin 100 mg intravenously* This was repeated after 4 hours, when she was also given oral aureomycin 1 5 g, *followed* at 6 hourly intervals by 1 g and then 0 5 g The drug was then continued at the rate of *0 5 g 6 hourly* until April 19

Treatment and Progress

The white cell count was then 8000 per c mm with only 38% of polymorphs A course of corticotrophin (25 mg 6 hourly) was begun, but after 200 mg had been given her condition continued to worsen and cortisone was *substituted* At first only 10 mg 4 hourly could be given, but after 1 day this was increased to 25 mg 4 hourly By that evening the patient was desperately ill, with a blood pressure *of 55/?* An intravenous infusion of noradrenaline was given with some temporary improvement in the blood pressure *On April 23 the dose of cortisone* was *raised* to 300 mg a day, *but she died the same evening* The blood urea then was 380 mg per 100 ml

Post mortem Findings

There was mucopus in the trachea and bronchi, and nodular congested areas in both lower lobes Brownish grey pus *could be expressed* from these areas There was no pleural eaction The abdominal viscera, endocrine organs, heart, nd brain appeared normal

Histological examination revealed no arterial abnormality

Discussion

Thomas (1950) suggested the division of Stevens Johnson syndrome (erythema multiforme exudativum) into two groups—major and minor The "major" type is associated with long-continued fever and severe conjunctivitis, the "minor" with predominantly skin lesions All five of the above cases seem to belong to the "major" category, though perhaps case 2 was intermediate

None of the patients had the genital lesions which have often been described, but this does not seem to be an essential part of the syndrome The tendency to recurrence is well illustrated by case 3 and to a lesser extent by case 2 However, even after severe and repeated attacks, eventual complete remission seems likely (case 3)

Fatal cases of this syndrome are rather rare, and cases 1 and 5 are therefore of special interest The atypical pneumonia is a common accompaniment of the syndrome, but the histological and macroscopic changes in case 1 have not been previously described In the few published accounts of necropsies following Stevens Johnson syndrome I have not been able to find any reference to arterial lesions

The clinical picture of Wegener's granulomatosis is described by Johnsson (1948) Rhinitis is the initial symptom, followed by a necrotic process in the nose, throat, and respiratory tract The patient appears to have a septicæmic illness with a high sedimentation-rate Terminally there is uræmia and hypertension No characteristic rash is described by Johnsson, but in a review by Fahey et al (1954) and in a recent article (Walton and Leggat 1956) patients are described with petechial rashes and with hæmorrhagic necrotising lesions, particularly over the elbows Ulceration of the mouth and chemosis are also mentioned by these authors

It may therefore be argued that case 1 was, clinically as well as pathologically, one of Wegener's granulomatosis rather than Stevens Johnson syndrome, but I feel that the clinical diagnosis of Stevens Johnson syndrome was undoubtedly justified Both conditions are thought to have an allergic background, the tissues becoming sensitive to products of necrosis, to drugs, or eventually to many stimuli There is no suggestion of drug allergy in this case One may look upon it as a case of Wegener's granulomatosis presenting as Stevens-Johnson syndrome, or of Wegener's granulomatosis simulating Stevens Johnson syndrome

Polyarteritis is also found in certain cases of "drug sensitivity"—to sulphonamides (Hartroft 1944, More et al 1946), thiourea (Gibson and Quinlan 1945, Dalgleish 1952), and phenylbutazone (O'Brien and Storey 1954) A case of Stevens Johnson syndrome following phenylbutazone therapy has been described (Steel and Moffatt 1954) It is always difficult, however, to prove that drug allergy is really responsible In case 2 the long-term treatment with thiouracil was considered as a possible causal factor, and attempts were made to prove sensitivity to this drug

Standard textbooks on allergy are not at all helpful in this respect It is generally agreed that though the formation of "haptens" provides a convenient theoretical explanation of drug allergy, there are apparently no circulating antibodies, and therefore the conventional methods of skin testing are useless However, an article by Rajka and Hegyi (1950) suggested that the "distant reversed Prausnitz Küstner (P K) reaction" is a reliable means of demonstrating drug allergy

First the P K method of demonstrating transferred sensitivity was tried (Prausnitz and Küstner 1921)

In this method the skin of the back of a normal person is used Intradermal injections are made—two of 0 1 ml of the supposedly sensitive person's serum, and two of 0 1 ml of normal serum 24 hours later 0 02 ml of the suspected agent is injected into one "sensitised" and one control site, and 0 02 ml of normal saline into the other two sites A positive reaction is characterised by the development of a weal and flare into the one area where the allergen is in contact with the sensitised skin All the other control sites should show no reaction

Three normal people were thus tested with the serum of case 2 An injectable form of thiouracil was difficult to obtain since this drug is almost insoluble in water It seemed reasonable to suppose, however, that the serum of a patient under treatment with thiouracil would contain enough of the drug, either free or combined with serum protein Such a serum was used in 0 05 ml doses as the second injection in these tests, and none of the three tests was positive

The distant reversed P K reaction was then tried

Here, a patient under treatment with the suspected drug is injected intradermally with 0 05 ml of the potentially sensitive person's serum A control injection of normal serum is also given, and a positive reaction is characterised by a weal and flare which is confined to the test site

This test was carried out on three patients who were having thiouracil, using the serum of case 2 The first gave a negative result, the other two gave an apparently positive result with weal and flare definitely exceeding those at the control sites However, when similar tests were made in persons who had never had thiouracil, a similar picture was obtained Apparently some non-specific irritant had appeared in the serum of case 2, though it had been stored under aseptic conditions in a refrigerator No control of this type is mentioned by Rajka and Hegyi

It is interesting here to mention the findings in a case of undoubted methylthiouracil sensitivity encountered at the same time Fever, tachycardia, and considerable malaise developed when this patient took methylthiouracil Propylthiouracil was tolerated normally It was proved beyond doubt by repeated (accidental) exhibition of methylthiouracil that this was a specific sensitivity Yet here again the direct P K reaction (three tests) and the distant reversed P K reaction (four tests) were negative

The results of these tests suggest that the distant reversed P K test as proposed by Rajka and Hegyi is of no help in proving or disproving drug allergy Further disadvantages are evident from their article—the reactions were never positive in all test subjects and no indication is given of what proportion may be expected to give satisfactory results It is doubtful whether the differences between the sizes of the weals and flares in positive and control sites were significant, and the possibility of non-specific positive results such as I have found was apparently not considered

It is suggested therefore that a very critical approach should be made in attributing cases of Stevens Johnson syndrome to drug allergy Case 1 had no sulphonamides or other probable allergen Case 2 had only thiouracil. Case 3 seemed to improve when sulphonamides were exhibited in one of her attacks Case 4 had no potentially sensitising drugs Case 5 might have been due to sulphonamides but the time relationship makes this unlikely. It seems probable that the infections for which the various antibacterial agents were given could be the precipitating cause of the syndrome

Aureomycin and chloramphenicol have been said to produce improvement in some cases of Stevens Johnson syndrome These antibiotics did not seem to help in case 1 or case 5 but of course these patients were desperately ill when the course of treatment was begun Cortisone and corticotrophin are reported to "cure" the syndrome (Caldwell 1953), and this is adduced as further evidence of an allergic basis for the condition.

It is not, however, certain that the anti-allergic properties of these drugs are necessarily responsible for the " cures ", or indeed that the improvement was not due to spontaneous remission Thus in case 4 an exacerbation occurred while cortisone treatment was continuing The subsequent improvement followed the simultaneous administration of penicillin and corticotrophin, and it is impossible *to give credit to one rather than to the other*

Hence the cause of this syndrome is still obscure The hypothesis of drug allergy has not been supported by *any convincing proof*—and indeed it is shown that this mechanism is very difficult to prove The apparently satisfactory responses to antibiotics and to cortisone and corticotrophin are also suspect in a disorder which is usually self-limiting, and is liable to apparently spontaneous remissions and relapses

Summary

Five cases of Stevens Johnson syndrome are described Two were fatal, and one showed unusual post-mortem changes

One followed a long course of thiouracil therapy The difficulties of proving drug allergy are described

The cause of this syndrome remains obscure, and the therapeutic efficacy of antibiotics, cortisone, and corticotrophin are not proven

The cases were under the care of the late Dr D S Stevenson, the late Dr W R Snodgrass, and Sir John McNee in the Western Infirmary, Glasgow, and of Dr J S Parkinson and Dr W Mackay in Hope Hospital, Salford The supplies of cortisone and corticotrophin used in cases 4 and 5 were provided by Dr J S Parkinson I am indebted to Dr J Stewart for the necropsy and histological reports in case 1, and to Dr J D Hepplestone for those in case 5 Dr A J Macleod kindly provided a report on the progress of case 3

The photographs were provided by the Salford Group Clinical Photography Department

SUBACUTE combined degeneration of the spinal cord is caused by deficiency of vitamin B_{12} (Castle's extrinsic factor), the absorption of which is impaired by lack of *intrinsic factor* In patients with the typical history of peripheral paræsthesiæ associated with paresis, clear neurological signs, megaloblastic anæmia, and achlorhydria, the diagnosis is not in doubt, but such a clear clinical picture is by no means always found At times a good response to vitamin B_{12} has been used as a criterion in the diagnosis of subacute combined degeneration, and latterly the serum-vitamin-B_{12} level has been used for the same purposes Unfortunately the estimation of the serum-vitamin-B_{12} level is technically difficult, and the result is valueless if the patient has received parenteral vitamin B_{12} Furthermore, the serum level may be low because of a defect of absorption unrelated to the production of intrinsic factor

The most satisfactory way of establishing the diagnosis is to demonstrate that the patient cannot absorb vitamin B_{12} This vitamin contains cobalt and can conveniently be labelled with its radio isotopes, ^{60}Co or ^{58}Co, and there are four possible techniques which may be used

(1) Radioactive vitamin B_{12} is given and eight hours later a blood sample is taken (Booth and Mollin 1956) This technique necessitates a high dose (5 μC) of material labelled with ^{58}Co, and venepuncture after an interval which makes it impracticable for outpatients

(2) Arias et al (1955) assessed the radioactivity of the liver with a collimator ten days after an oral dose of radioactive B_{12}, after a subcutaneous dose, and after an oral dose with intrinsic factor This test is long and cumbersome, and surface counting over the liver may be inaccurate

(3) Radioactive vitamin B_{12} is given by mouth and the radioactivity of the stools measured over four to nine days, the amount absorbed being calculated by subtraction (Halstead et al 1956) The technical disadvantages are obvious

(4) Schilling et al (1955) estimated the urinary excretion in the twenty four hours following an oral dose of vitamin B_{12} labelled with ^{60}Co They showed that in 18 controls, 7–22% of the ingested radioactive material was excreted in the urine in twenty four hours Of 31 patients with achlorhydria but without blood dyscrasia, 24 excreted amounts equal to those in the control series, the remaining 7 excreted smaller but appreciable amounts In 35 patients with pernicious anæmia the excretion was usually 1% or less (maximum 2 3%)

We have applied this last technique to the investigation of neurological disorders, using vitamin B_{12} labelled with ^{58}Co, which has a half-life of seventy two days and is virtually free from risk In our series no patient under 45 was tested and the dose was of the order of 0 5 μC

Methods

Because of the relatively long half-life of ^{58}Co the tracer doses for use over a month or two can be dispensed in a single batch The radioactive vitamin B_{12} is diluted to give 0 5 μC per ml , and inactive B_{12} is added to bring the concentration to 3 μg per ml Accurate 1 ml quantities of the solution are transferred to glass ampoules, which are then sealed off At the same time a 1 in 1000 dilution of this solution is prepared as a standard for the estimation of the radioactivity in urine when the test is performed The preparation is carried out with sterile glassware, and the ampoules are boiled for ten minutes after sealing as a further precaution against contamination with micro organisms that might metabolise the vitamin B_{12} The standard is also made up in *N*/10 hydrochloric acid to preserve sterility, and sufficient cobalt chloride is added to it to impart a definite pink colour to the solution This makes it easily recognisable, and may also reduce the liability to adsorption on to the glass The standard solution is divided into several portions, which are kept in well-stoppered bottles until needed One bottle will serve for several tests, but fresh bottles should be used from time to time to avoid the possible accumulation of errors due to evaporation and contamination, and it is wise, on opening a fresh bottle, to check the old standard against the new

When a test is to be performed, the contents of one ampoule of the prepared solution of activity 0 5 μC are transferred to a suitable drinking-vessel and made up to 100 ml. with water The procedure is then as follows

(1) *Zero Hour* —Light breakfast, but no further food until after zero + $4^1/_2$ hours

(2) *Zero + $2^1/_2$ Hours* —The bladder is emptied The prepared radioactive vitamin B_{12} is given in 100 ml of water by mouth All urine is now collected for twenty-four hours, avoiding fæcal contamination

(3) *Zero + $4^1/_2$ Hours* —1000 µg of ordinary vitamin B_{12} is given intramuscularly to ensure a high level in the serum and maximum excretion

10 ml of the twenty-four hour urine collection is assayed on an 'Ekco N550' scintillation counter, and the counting-rate is compared with that given by 10 ml of the standard, due correction being made for background and dead-time Since the quantity of radioactive material actually given to the patient is equal to that contained in 1 litre of the standard, the fraction excreted is computed as follows

$$\text{Percentage of tracer excreted} = \frac{\text{Count-rate of urine} \times \text{vol (litres)} \times 100}{\text{Count rate of standard}}$$

If defective absorption is demonstrated the test is repeated, but this time 100 mg of intrinsic factor is mixed with the radioactive vitamin B_{12} If the patient still fails to excrete the radioactive material at the normal levels, the primary abnormality is not defective production of intrinsic factor and the condition is not subacute combined degeneration

Results

Normal Subjects —Schilling et al (1955) found that the normal range of excretion using this technique was 7–22% of the ingested dose To establish our own standards we tested 5 normal subjects The range of excretion in this series was 4 0–7 1%, and we feel that the figures obtained are satisfactorily free from experimental error It is possible that our lower figures may be due to the age of the subjects studied, for none was under 45 years of age

Patients with Subacute Combined Degeneration —10 patients with classical subacute combined degeneration were subjected to the test They had already been followed for periods of two to seventeen years and had responded to liver or vitamin B_{12} The excretion-range in these cases was 0 3–1 0% (average 0 6%) Thus there is a clear difference between these figures and those for the normals In 4 patients the test was repeated seven days later with the addition of 100 mg of intrinsic factor to the dose of radioactive vitamin B_{12} The excretion-range rose to levels of 4 1–6 0% (average 5 2%) (see table)

Patients with Doubtful Diagnosis of Subacute Combined Degeneration —These comprised the following groups

(a) Subacute myeloneuropathy with achlorhydria (6 patients)

(b) Syndromes similar to (a), with a partial therapeutic response to either vitamin B_{12} or liver extract (4 patients)

(c) A clinical story suggesting subacute combined degeneration of the cord, free acid in gastric juice (3 patients)

(d) Diabetes and neurological manifestations (2 patients)

RESULTS OF EXCRETION TESTS IN 10 CASES OF SUBACUTE COMBINED DEGENERATION WITH HISTAMINE FAST ACHLORHYDRIA

Case no	Age (yr)	Sex	Hb (%)	R B C (in millions per c mm)	Colour index	Marrow	B_{12} excretion (%)	B_{12} excretion after administration of intrinsic factor (%)

Illustrative Case-records

MYELONEUROPATHY WITH ACHLORHYDRIA

Case 11 —A man, aged 52, developed pins and needles in the feet in January, 1956 This symptom became worse and spread to the hands He was admitted to the Manchester Royal Infirmary in July with diminished tendon reflexes, equivocal plantar responses, impaired superficial sensation to the mid calf in both legs, and impaired position sense, in the toes Vibration sense was normal

Blood count, marrow, and liver function tests normal Pyruvate tolerance curve fasting 1 9 mg per 100 ml at 1 hr 2 3 mg per 100 ml, at 2 hr 2 2 mg per 100 ml Histamine fast achlorhydria

Clinically, there was a clear indication of a combined cord and peripheral nerve lesion This, together with a history of chronic alcoholism, and the abnormal pyruvate tolerance, led us to believe that the most probable diagnosis was peripheral neuropathy, possibly due to aneurine (vitamin B_1) deficiency The vitamin-B_{12} excretion test showed that his urinary excretion was 5 3% of the ingested dose in twenty-four hours This ruled out absolutely the alternative diagnosis of subacute combined degeneration The disorder responded to aneurine

MYELONEUROPATHY WITH ACHLORHYDRIA PARTIAL RESPONSE TO VITAMIN B_{12}

Case 12 —In 1951 a man, aged 43, noticed vague discomfort in the left leg which became worse A year later his knee jerks were diminished and ankle jerks absent, plantar responses flexor, and sensation normal In July, 1954, he had extensor plantar responses and the knee jerks were absent, sensation was still normal

Wassermann reactions (W R) of blood and cerebrospinal fluid (C S F) negative C S F normal Radiographs of dorso-lumbar spine, normal Histamine fast achlorhydria Peripheral blood count normal, marrow not examined

The patient was given vitamin B_{12} 100 µg daily for three weeks After three or four days his symptoms cleared up completely, but although the vitamin B_{12} was continued fortnightly, his symptoms recurred with aching pains in the legs The vitamin B_{12}-excretion test in May, 1956, showed that 6 4% of the dose was excreted This, we concluded, ruled out subacute combined degeneration

MYELONEUROPATHY WITH ACHLORHYDRIA PARTIAL RESPONSE TO VITAMIN B_{12}

Case 13 —In 1946 a man, aged 48, began to have an unsteady gait, heaviness of the legs, and tingling in his feet He had extensor plantar responses, impaired deep sensation in the toes, and diminished ankle and knee jerks

Blood count, marrow, C S F all normal, histamine fast achlorhydria W R negative in blood and C S F

From 1949 onwards he was treated with 'Anahæmin' or vitamin B_{12} After six months he was symptomatically improved, but clinical findings were unchanged In September, 1950, his left foot dragged, and he gradually deteriorated In November, 1953, spastic paresis necessitated a mechanically propelled chair In a vitamin B_{12} excretion test in September, 1956 4 4% of the ingested dose was excreted indicating that he had not subacute combined degeneration, but the spinal form of disseminated sclerosis

DIABETES WITH NEUROLOGICAL COMPLICATIONS

Case 14 —In 1950 a man, aged 60, was *found* to have diabetes, which was controlled well with insulin and restricted diet In May, 1956, during an upper respiratory infection, his diabetes became uncontrolled and he was admitted to hospital He had had no neurological symptoms, but was found to have diminished knee jerks, absent ankle jerks, extensor plantar responses and impaired superficial sensation to mid calf, his vibration sense was lost, and his position sense was good

His diabetes was treated in the routine fashion but his neurological signs did *not* change Blood count and chest X ray normal, W R negative

It was felt that his neurological signs were probably due to diabetic myeloneuropathy In a vitamin B_{12} excretion test 7 0% of the dose was excreted in twenty four hours Subacute combined degeneration was thus excluded

It is not, however, certain that the anti allergic properties of these drugs are necessarily responsible for the " cures ", or indeed that the improvement was not due to spontaneous remission Thus in case 4 an exacerbation occurred while cortisone treatment was continuing The subsequent improvement followed the simultaneous administration of penicillin and corticotrophin, and it is impossible to give credit to one rather than to the other

Hence the cause of this syndrome is still obscure The hypothesis of drug allergy has not been supported by any convincing proof—and indeed it is shown that this mechanism is very difficult to prove The apparently satisfactory responses to antibiotics and to cortisone and corticotrophin are also suspect in a disorder which is usually self-limiting, and is liable to apparently spontaneous remissions and relapses

Summary

Five cases of Stevens Johnson syndrome are described Two were fatal, and one showed unusual post mortem changes

One followed a long course of thiouracil therapy The difficulties of proving drug allergy are described

The cause of this syndrome remains obscure, and the therapeutic efficacy of antibiotics, cortisone, and corticotrophin are not proven

The cases were under the care of the late Dr D S Stevenson, the late Dr W R Snodgrass, and Sir John McNee in the Western Infirmary, Glasgow, and of Dr J S Parkinson and Dr W Mackay in Hope Hospital, Salford The supplies of cortisone and corticotrophin used in cases 4 and 5 were provided by Dr J S Parkinson I am indebted to Dr J Stewart for the necropsy and histological reports in case 1, and to Dr J D Hepplestone for those in case 5 Dr A J Macleod kindly provided a report on the progress of case 3

SUBACUTE combined degeneration of the spinal cord is caused by deficiency of vitamin B_{12} (Castle's extrinsic factor), the absorption of which is impaired by lack of intrinsic factor In patients with the typical history of peripheral paræsthesiæ associated with paresis, clear neurological signs, megaloblastic anæmia, and achlorhydria, the diagnosis is not in doubt, but such a clear clinical picture is by no means always found At times a good response to vitamin B_{12} has been used as a criterion in the diagnosis of subacute combined degeneration, and latterly the serum-vitamin-B_{12} level has been used for the same purposes Unfortunately the estimation of the serum-vitamin-B_{12} level is technically difficult, and the result is valueless if the patient has received parenteral vitamin B_{12} Furthermore, the serum level may be low because of a defect of absorption unrelated to the production of intrinsic factor

The most satisfactory way of establishing the diagnosis is to demonstrate that the patient cannot absorb vitamin B_{12} This vitamin contains cobalt and can conveniently be labelled with its radio isotopes, ^{60}Co or ^{58}Co, and there are four possible techniques which may be used

(1) Radioactive vitamin B_{12} is given and eight hours later a blood sample is taken (Booth and Mollin 1956) This technique necessitates a high dose (5 μC) of material labelled with ^{58}Co, and venepuncture after an interval which makes it impracticable for outpatients

(2) Arias et al (1955) assessed the radioactivity of the liver with a collimator ten days after an oral dose of radioactive B_{12}, after a subcutaneous dose, and after an oral dose with intrinsic factor This test is long and cumbersome, and surface counting over the liver may be inaccurate

(3) Radioactive vitamin B_{12} is given by mouth and the radioactivity of the stools measured over four to nine days, the amount absorbed being calculated by subtraction (Halstead et al 1956) The technical disadvantages are obvious

(4) Schilling et al (1955) estimated the urinary excretion in the twenty four hours following an oral dose of vitamin B_{12} labelled with ^{60}Co They showed that in 18 controls, 7–22% of the ingested radioactive material was excreted in the urine in twenty four hours Of 31 patients with achlorhydria but without blood dyscrasia, 24 excreted amounts equal to those in the control series, the remaining 7 excreted smaller but appreciable amounts In 35 patients with pernicious anæmia the excretion was usually 1% or less (maximum 2 3%)

We have applied this last technique to the investigation of neurological disorders, using vitamin B_{12} labelled with ^{58}Co, which has a half-life of seventy two days and is virtually free from risk In our series no patient under 45 was tested and the dose was of the order of 0 5 μC

Methods

Because of the relatively long half-life of ^{58}Co the tracer doses for use over a month or two can be dispensed in a single batch The radioactive vitamin B_{12} is diluted to give 0 5 μC per ml, and inactive B_{12} is added to bring the concentration to 3 μg per ml Accurate 1 ml quantities of the solution are transferred to glass ampoules, which are then sealed off At the same time a 1 in 1000 dilution of this solution is prepared as a standard for the estimation of the radioactivity in urine when the test is performed The preparation is carried out with sterile glassware, and the ampoules are boiled for ten minutes after sealing as a further precaution against contamination with micro organisms that might metabolise the vitamin B_{12} The standard is also made up in *N*/10 hydrochloric acid to preserve sterility, and sufficient cobalt chloride is added to it to impart a definite pink colour to the solution This makes it easily recognisable, and may also reduce the liability to adsorption on to the glass The standard solution is divided into several portions, which are kept in well stoppered bottles until needed One bottle will serve for several tests, but fresh bottles should be used from time to time to avoid the possible accumulation of errors due to evaporation and contamination, and it is wise, on opening a fresh bottle, to check the old standard against the new

When a test is to be performed, the contents of one ampoule of the prepared solution of activity 0 5 μC are transferred to a suitable drinking vessel and made up to 100 ml with water The procedure is then as follows

(1) *Zero Hour.*—Light breakfast, but no further food until after zero + $4^1/_2$ hours.

(2) *Zero + $2^1/_2$ Hours.*—The bladder is emptied. The prepared radioactive vitamin B_{12} is given in 100 ml. of water by mouth. All urine is now collected for twenty-four hours, avoiding fæcal contamination.

(3) *Zero + $4^1/_2$ Hours.*—1000 µg. of ordinary vitamin B_{12} is given intramuscularly to ensure a high level in the serum and maximum excretion.

10 ml. of the twenty-four hour urine collection is assayed on an 'Ekco N550' scintillation counter, and the counting-rate is compared with that given by 10 ml. of the standard, due correction being made for background and dead-time. Since the quantity of radioactive material actually given to the patient is equal to that contained in 1 litre of the standard, the fraction excreted is computed as follows:

$$\text{Percentage of tracer excreted} = \frac{\text{Count rate of urine} \times \text{vol. (litres)} \times 100}{\text{Count rate of standard}}$$

If defective absorption is demonstrated the test is repeated, but this time 100 mg. of intrinsic factor is mixed with the radioactive vitamin B_{12}. If the patient still fails to excrete the radioactive material at the normal levels, the primary abnormality is not defective production of intrinsic factor and the condition is not subacute combined degeneration.

Results

Normal Subjects.—Schilling et al. (1955) found that the normal range of excretion using this technique was 7–22% of the ingested dose. To establish our own standards we tested 5 normal subjects. The range of excretion in this series was 4.0–7.1%, and we feel that the figures obtained are satisfactorily free from experimental error. It is possible that our lower figures may be due to the age of the subjects studied, for none was under 45 years of age.

Patients with Subacute Combined Degeneration.—10 patients with classical subacute combined degeneration were subjected to the test. They had already been followed for periods of two to seventeen years and had responded to liver or vitamin B_{12}. The excretion-range in these cases was 0.3–1.0% (average 0.6%). Thus there is a clear difference between these figures and those for the normals. In 4 patients the test was repeated seven days later with the addition of 100 mg. of intrinsic factor to the dose of radioactive vitamin B_{12}. The excretion-range rose to levels of 4.1–6.0% (average 5.2%) (see table).

Patients with Doubtful Diagnosis of Subacute Combined Degeneration.—These comprised the following groups:

(*a*) Subacute myeloneuropathy with achlorhydria (6 patients).

(*b*) Syndromes similar to (*a*), with a partial therapeutic response to either vitamin B_{12} or liver extract (4 patients).

(*c*) A clinical story suggesting subacute combined degeneration of the cord, free acid in gastric juice (3 patients).

(*d*) Diabetes and neurological manifestations (2 patients).

RESULTS OF EXCRETION TESTS IN 10 CASES OF SUBACUTE COMBINED DEGENERATION WITH HISTAMINE-FAST ACHLORHYDRIA

Illustrative Case-records

MYELONEUROPATHY WITH ACHLORHYDRIA

Case 11.—A man, aged 52, developed pins and needles in the feet in January, 1956. This symptom became worse and spread to the hands. He was admitted to the Manchester Royal Infirmary in July with diminished tendon reflexes, equivocal plantar responses, impaired superficial sensation to the mid calf in both legs, and impaired position sense in the toes. Vibration sense was normal.

Blood count, marrow, and liver function tests normal. Pyruvate tolerance curve: fasting 1.9 mg. per 100 ml., at 1 hr. 2.3 mg. per 100 ml., at 2 hr. 2.2 mg. per 100 ml. Histamine-fast achlorhydria.

Clinically, there was a clear indication of a combined cord and peripheral-nerve lesion. This, together with a history of chronic alcoholism, and the abnormal pyruvate tolerance, led us to believe that the most probable diagnosis was peripheral neuropathy, possibly due to aneurine (vitamin B_1) deficiency. The vitamin-B_{12} excretion test showed that his urinary excretion was 5.3% of the ingested dose in twenty-four hours. This ruled out absolutely the alternative diagnosis of subacute combined degeneration. The disorder responded to aneurine.

MYELONEUROPATHY WITH ACHLORHYDRIA: PARTIAL RESPONSE TO VITAMIN B_{12}

Case 12.—In 1951 a man, aged 43, noticed vague discomfort in the left leg which became worse. A year later his knee-jerks were diminished and ankle-jerks absent, plantar responses flexor, and sensation normal. In July, 1954, he had extensor plantar responses and the knee-jerks were absent; sensation was still normal.

Wassermann reactions (W.R.) of blood and cerebrospinal fluid (C.S.F.) negative. C.S.F. normal. Radiographs of dorsolumbar spine, normal. Histamine-fast achlorhydria. Peripheral blood count normal; marrow not examined.

The patient was given vitamin B_{12} 100 µg. daily for three weeks. After three or four days his symptoms cleared up completely, but although the vitamin B_{12} was continued fortnightly, his symptoms recurred with aching pains in the legs. The vitamin B_{12} excretion test in May, 1956, showed that 6.4% of the dose was excreted. This, we concluded, ruled out subacute combined degeneration.

MYELONEUROPATHY WITH ACHLORHYDRIA: PARTIAL RESPONSE TO VITAMIN B_{12}

Case 13.—In 1946 a man, aged 48, began to have an unsteady gait, heaviness of the legs, and tingling in his feet. He had extensor plantar responses, impaired deep sensation in the toes, and diminished ankle and knee jerks.

Blood count, marrow, C.S.F. all normal; histamine-fast achlorhydria. W.R. negative in blood and C.S.F.

From 1949 onwards he was treated with 'Anahæmin' or vitamin B_{12}. After six months he was symptomatically improved, but clinical findings were unchanged. In September, 1950, his left foot dragged, and he gradually deteriorated. In November, 1953, spastic paresis necessitated a mechanically propelled chair. In a vitamin B_{12} excretion test in September, 1956, 4.4% of the ingested dose was excreted, indicating that he had not subacute combined degeneration, but the spinal form of disseminated sclerosis.

DIABETES WITH NEUROLOGICAL COMPLICATIONS

Case 14.—In 1950 a man, aged 60, was found to have diabetes, which was controlled well with insulin and restricted diet. In May, 1956, during an upper respiratory infection, his diabetes became uncontrolled and he was admitted to hospital. He had had no neurological symptoms, but was found to have diminished knee-jerks, absent ankle-jerks, extensor plantar responses and impaired superficial sensation to mid calf; his vibration sense was lost, and his position sense was good.

His diabetes was treated in the routine fashion but his neurological signs did not change. Blood count and chest X ray normal; W.R. negative.

It was felt that his neurological signs were probably due to diabetic myeloneuropathy. In a vitamin-B_{12} excretion test 7.0% of the dose was excreted in twenty-four hours. Subacute combined degeneration was thus excluded.

This case may be contrasted with the following

DIABETES WITH NEUROLOGICAL MANIFESTATIONS DUE TO SUBACUTE COMBINED DEGENERATION

Case 15 —In 1938 a man, aged 51, began to have classical symptoms of diabetes (blood sugar 281 mg per 100 ml) He was treated with diet and insulin but control was not satisfactory In 1952 he had weakness of the right hand of sudden onset which recovered to some extent, leaving the hand tingling In 1953 his tongue was sore and he was given vitamin B complex Shortly after this he had the first of eight or nine attacks of loss of consciousness, which were felt to be due to cerebral arteriopathy Later his left foot became numb and heavy and his fingers tingled In 1954 he had intermittent claudication In August, 1955, he had superficial glossitis and no pulses were palpable in either leg Examination otherwise was normal

His blood sugar was 246 mg per 100 ml , red cells 3,910,000 per c mm , hæmoglobin 84%, colour-index 1 07 In December, 1955, he complained of definite loss of sensation in both feet

On Nov 3, 1956, he had another blackout Though his tendon reflexes were normal, the plantar responses were doubtful and he had a glove and stocking type of sensory loss to pin-prick and cotton wool Blood red cells 2,970,000 per c mm , hæmoglobin 70%, colour index 1 19 Sternal marrow increased activity of the red-cell series with intermediate megaloblasts and some pro erythroblasts Histamine fast achlorhydria Air encephalogram slight ventricular dilatation Electro encephalogram some slowing of the resting rhythms, suggesting cerebral arteriosclerosis

In a vitamin-B_{12} excretion test only 0 3% of the ingested dose was excreted When, ten days later, the test was repeated with 100 mg of intrinsic factor, the excretion rose to 4 1% Accordingly, subacute combined degeneration was diagnosed independently of the diabetes, and he was given vitamin B_{12} regularly Three months later his neurological symptoms had cleared, and his general condition had improved considerably, his hæmoglobin was 92%

MYELONEUROPATHY WITH FREE ACID IN STOMACH PARTIAL RESPONSE TO VITAMIN B_{12}

Case 16 —In 1952 a man, aged 56, noticed tingling in both hands and both legs, and found that he could not distinguish objects by touch He was liable to stumble, and his legs felt heavy In February, 1954, he had brisk tendon reflexes , extensor plantar responses , impaired superficial sensation in both lower limbs to the mid thigh, and in the upper limbs to the mid forearm , absent vibration sense , position sense slightly impaired

Radiographic examination of the cervical spine showed advanced osteo arthritis Blood and cerebrospinal fluid normal Free acid in the gastric juice W R negative in blood and C S F Marrow not examined

The patient was treated with vitamin B_{12} 100 µg daily for three weeks, and then twice weekly Later in 1954 he considered himself almost back to normal save for numbness in the hands, but in June, 1956, his plantar responses were still abnormal, and sensory changes still present in arms and legs In a vitamin-B_{12} excretion test 11 7% of the ingested dose was excreted in twenty-four hours The correct diagnosis is probably cervical spondylosis.

Discussion

In these doubtful cases the excretion test gave figures from 3% to 12%—well above the range for the proven cases of subacute combined degeneration In case 15 the coexistence of diabetes and subacute combined degeneration was established by the abnormally low excretion of vitamin B_{12} We feel that clinical use of this test in investigating neurological disorders is well justified The technique is safe and relatively easy to apply, and the experimental error is negligible

So far we have applied the tests to only 3 cases of so-called " subacute combined degeneration of the spinal cord " in which there was free acid in the stomach , and in each of these cases vitamin B_{12} was absorbed normally We are anxious to investigate further such cases It seems likely that the controversy over the diagnostic value of achlorhydria in subacute combined degeneration will be resolved by the vitamin-B_{12} excretion test, which will also render the fractional test meal outmoded as the ultimate diagnostic investigation in this condition

Investigation of the myeloneuropathies is often complicated by the fact that the patients have received injections of liver or vitamin B_{12}, when marrow examination and serum-vitamin-B_{12} levels are misleading, but the excretion test remains unaffected Thus in doubtful cases treatment with vitamin B_{12} may be begun before the excretion test It is possible, therefore, to accumulate a series of cases while a batch of radioactive material is being prepared, and yet lose no time in beginning vitamin-B_{12} therapy, which may or may not be continued after the test

In future, patients may be found with excretion figures on the lowest level of the normal range In them the diagnosis may be doubtful It will be reasonable to prescribe vitamin B_{12} and repeat the test later, to see whether absorption has further diminished In this way an incipient neural lesion will have been corrected at the earliest opportunity

Summary

Confirmation of the diagnosis in uncertain cases of subacute combined degeneration of the spinal cord depends on demonstrating incapacity to absorb vitamin B_{12}

Results of an excretion test with radioactive vitamin B_{12} in normal subjects, in classical cases of subacute combined degeneration of the cord, and in a series of patients in whom the diagnosis was in doubt showed that this test confirms or excludes the diagnosis with reasonable certainty

The vitamin B_{12} labelled with ^{56}Co was supplied to us through the kind offices of Dr E Lester Smith, of Glaxo Laboratories Ltd , and the intrinsic factor by Lederle Ltd We are especially grateful to Dr F R Ferguson and Dr G E Smyth for permission to study the cases under their care, and to Prof Robert Platt and Dr Ferguson for helpful criticism and advice

REVIEW OF
910 CASES OF BRONCHIAL CARCINOMA
WITH RESULTS OF TREATMENT

CONSULTING SURGEON

ROYAL INFIRMARY, MANCHESTER

There is no need to emphasise the appalling frequency of bronchial carcinoma, for unfortunately it is too obvious But, though several large series of cases have been reviewed recently, it seemed to us opportune to add another series from Manchester The patients in this series of 910 consecutive investigated cases of proved bronchial carcinoma were seen and treated by two of us (A G B and W F N) at the Manchester Royal Infirmary during the seven years 1948–54 inclusive They do not include a number of obviously inoperable patients whom we saw during this period but did not investigate and assess for operative treatment

Clinical Features

Symptoms.—The most common symptom is cough, but it is so usual in the industrial area from which the patients were largely drawn, that many patients accept it as being of no importance. A gradual change in its character, especially to a hard intractable unproductive cough, may serve as a warning. Chest pain, recurrent bronchial obstruction with infection and fever, hæmoptysis, and increasing breathlessness will usually cause a patient to go to his doctor. Hoarseness, dysphagia, pain down the arm, venous obstruction, and severe loss of weight are late symptoms. There were several cases with pulmonary osteo arthropathy—all were inoperable, though in some more recent cases we have resected the tumour.

Duration of Symptoms.—This was deplorably long. On the average, after the onset of warning symptoms, six months elapsed before the patients attended our clinic. The lengths of histories were remarkably constant over the seven years (table I), though increasing prominence was being given to the subject.

TABLE I—AVERAGE DURATION OF SYMPTOMS BEFORE DIAGNOSIS

Year	Duration of symptoms (months)	Year	Duration of symptoms (months)
1948	6·9	1952	6·6
1949	6·3	1953	5·5
1950	6·9	1954	6·6
1951	6·8		

That this interval, during which the illness is progressing, is important for prognosis, is not only obvious, but is well exemplified in our series by those patients who were picked up by miniature or other routine radiography. Of 15 whose disease was thus discovered, 8 were able to have radical resections and 3 (a fifth of those seen) were well after three years. This is a small number, but encouraging when compared with the total results.

The duration of symptoms before diagnosis in the series of Overholt and Schmidt (1949) was eleven months in 1932–42 and ten months in 1947–48. The interval was found to be four and a half months by Taylor and Waterhouse (1950) and only three and a half months by Oswald (1956). In our cases the average duration of symptoms remained remarkably constant, though histories were taken by a variety of observers.

Morbid Anatomy

The two lungs were involved about equally commonly, the order of frequency according to lobes being left upper lobe, right upper lobe, right lower lobe, left lower lobe, left main bronchus, right main bronchus, right middle lobe, and least commonly the lingula (fig 1).

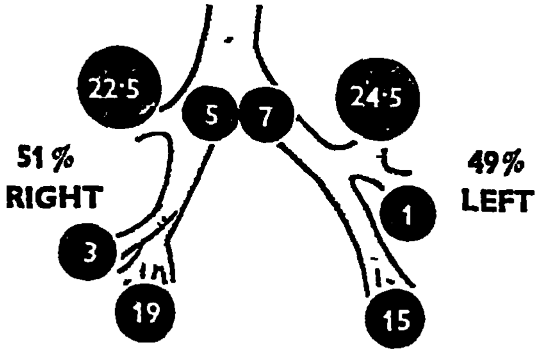

Fig 1—Incidence of tumours in various sites

TABLE II—PROGNOSIS IN DIFFERENT TUMOURS (414 CASES WITH HISTOLOGICAL DETAILS AVAILABLE)

Histological group	Squamous cell carcinoma	Adenocarcinoma	Oat cell carcinoma	Anaplastic carcinoma	Mixed salivary and transitional cell carcinoma	Sarcoma
Number (% of total series)	56	6	21	16	0·8	0·3
Resectable tumours (% of total resected)	69	8	12	8		
Three year survivors (% of total survivors)	85	10	2	2		

Any pathological description clearly applies only to the piece of tissue examined. This may not necessarily be representative. Only by serial sections of the whole tumour and its metastases can an exact histological diagnosis be made. The diagnosis in these cases was determined either by biopsy of a small fragment of tumour or by ordinary histological examination of the resected specimen.

In 414 cases, histological evidence of tumour was obtained. Of these, 56% were squamous cell carcinomas, 6% adenocarcinomas, and 21% oat-cell carcinomas. The rest consisted of spheroidal-cell (8%), anaplastic (8%), and mixed salivary and transitional cell (0·8%) carcinomas, and sarcoma (0·3%). These figures approximate to those of Kreyberg (1952). Reingold et al (1950) and Willis (1952) found several types of cell in a high proportion of the bronchial tumours they examined. In our series also, variations in histological pattern in the same tumour were seen, mainly as areas of differentiated cells in the anaplastic and spheroidal cell tumours. Where this differentiation was recognisable on histological examination, the tumour was labelled according to the differentiated part, without any attempt at grading.

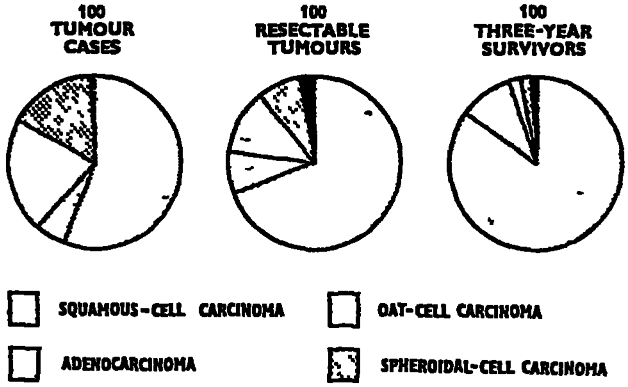

Fig 2—Cases classified according to histological type—operability and survival rates

The creation of separate groups of spheroidal cell and anaplastic carcinoma is fallacious. It results from varying custom in terminology among the pathologists concerned in our series. Most of the anaplastic carcinomas have almost certainly been of the spheroidal cell type. These two groups have therefore been united and termed spheroidal cell carcinomas.

Prognosis

Histology.—The operability-rate and expectation of life after resection were a great deal better for squamous cell carcinoma and adenocarcinoma than for other types of tumour. Oat cell and spheroidal cell neoplasms had an almost hopeless prognosis. This is shown in table II, and graphically illustrated in fig 2, in which the increased proportions of adenocarcinoma and squamous cell car-

TABLE III—EFFECT OF POSITION ON THREE-YEAR SURVIVAL RATE

Site (right)	Survivors (%)	Site (left)	Survivors (%)
Upper lobe	2 5	Upper lobe	4 5
Middle lobe	3 5	Lingula	37
Lower lobe	7	Lower lobe	6
Main bronchus	2	Main bronchus	1 5
All right lung	4 1	All left lung	5 2

cinoma are seen in those patients who had a resection, and still more notably in those who survive three years

Site—In Bignall and Moon's (1955) and Borrie's (1952) cases, prognosis was better when the growth was in the upper rather than in the lower lobes The reverse appears in our cases (table III) Prognosis was a little better with a growth in the left than in the right lung The three year survival-rate was highest in the 8 patients seen with lesions in the lingular bronchus (3 surviving) Tumours arising in the lower-lobe bronchi were found to have a better outlook than those arising anywhere else in the lung (except the lingula)

Sex—There were 70 women amongst the 910 patients, making the proportion of men to women 13 to 1 (a lower proportion of women than in other series) The prognosis was worse in women There were only 5 (7%) in whom resection was possible with any hope of cure, compared with 21% in the combined series Of the 53 women seen between 1948 and 1952, only 2 survived for three years (1 9% in contrast with 6 1% for the series as a whole) Factors which could be responsible for this were investigated The women did not have their symptoms longer than the men the average time between onset of symptoms and arrival at the chest clinic was six and a half months Their average age was 53, against 55 for the whole series The difference does not seem *significant*, and in any case, the average age in patients surviving three years was a little lower than the average for the series The distribution of the tumours in the various regions of the two lungs showed no significant difference from that in the series as a whole There was, however, a definite difference in the histological appearance of the tumours there were considerably fewer of the squamous-cell and many more oat-cell neoplasms, which on the whole give an almost hopeless prognosis This is shown in table IV and fig 3

TABLE IV—INCIDENCE OF EACH HISTOLOGICAL TYPE

Type	Women (%)	Whole series (%)
Squamous cell carcinoma	32	56
Adenocarcinoma	8	6
Oat cell carcinoma	44	21
Spheroidal cell carcinoma	14	16

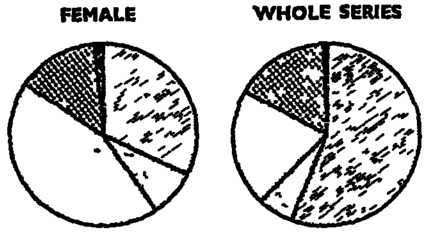

Fig 3—Cases classified according to histological type in each sex

General—There were 44 three year survivors among 720 cases seen between 1948 and 1952 These results correspond roughly to others published recently—Price Thomas (1955), Holmes Sellors (1955), and Bignall and Moon (1955) The number of cases was smaller, but the results were a little brighter They were considerably brighter than those of Taylor and Waterhouse (1950), this may well reflect the combination of improvement of technique and changing criteria of selection

The results cannot be judged as completely representative of all cases of lung carcinoma They come from a thoracic unit, where a certain amount of preselection has taken place before patients are referred Many obviously inoperable cases are thus excluded

Of 910 patients seen, 340 (37%) had thoracotomies, this proportion did not change appreciably in the years between 1948 and 1954 The resectability-rate, however, did change Of the 340 who had thoracotomies, 191 (56%) had radical operations with a hope of cure In the first five years, 52% of the thoracotomies led to a radical operation, this improved to 69% in the last two years of the series This was perhaps achieved by better selection of cases for operation It was not because the diagnosis was made earlier, but there has been some tendency for the operations to become more radical The opinion was held, at one time, that if a patient survived more than two years after operation he had a good chance of being cured This period has been found too short Holmes Sellors has shown that, for a feeling of security, three years must elapse In the years 1948 to 1952, of 720 patients seen, 255 (35%) had thoracotomies, of the latter, 132 (42%) came to radical operation and 44 survived three years—i e, 33 3% of the patients operated on with a hope of cure, and 6% of all patients seen during that period Of the patients seen from 1948 to 1950, 25 are still alive—i e, have survived five years or more (this is 28% of patients undergoing radical operation and 5 5% of all seen) The vast majority of the remainder are known to have died of a recurrence of the condition

Summary and Conclusions

910 cases of bronchogenic neoplasm were studied Only 6% survived for three years

On the average, patients were not seen till six months after the appearance of warning symptoms We must strive to persuade the public to recognise and take heed of these symptoms early, and not to neglect them for six months It is true that in those who died, the duration of symptoms was about the same as in those who survived three years—but the latter were fortunate, most having slowly growing squamous cell carcinomas or adenocarcinomas Those picked up early at routine radiography showed the best prognosis (3 of 15 survived for three years) The prognosis was best for squamous cell carcinoma, and almost hopeless for spheroidal cell, oat cell and *anaplastic tumours*

The best results in our series were obtained when the tumour was situated in the lingula (though the number was small and cannot be considered significant statistically) Of the rest, the results were better in the lower lobes than anywhere else in the bronchial tree

Prognosis in the women was considerably worse than in the men, probably because they had a larger proportion of oat cell and a smaller proportion of squamous cell neoplasms than did the men

The proportion of men to women with this disease was 13 to 1 The average age of all cases was 55 years, that of women 53 years, and that of three year survivors 53 years

It is a pleasure to thank Prof A C Campbell and Dr Raymond Whitehead for their help in the preparation of this paper, for much of it is based on work done in their department of pathology To Dr R G W Ollerenshaw we are grateful for the illustrations, and to Miss M Howarth for help with the records

ASSISTANT PATHOLOGIST, UNITED CARDIFF HOSPITALS

SEVERAL workers have reported the occurrence of pain after the taking of alcohol in some patients with Hodgkin's disease Of all patients with this disease, only a small proportion have been found to have the symptom, even when it is regularly sought Bichel and Bastrup-Madsen (1953) found it in 9 out of 62 cases No other difference has been found between those patients who do have it and those who do not The *British Medical Journal* (1956) states that "it does not seem to occur in other types of malignant lymphomata or other neoplastic conditions"

We describe here 2 patients with alcohol induced pain due, not to Hodgkin's disease, but to carcinoma; though the primary site was in slight doubt in both cases, it was almost certainly in the thymus in one and in the pancreas in the other

Case-reports

Case 1 —A married woman, then aged 47, was first seen in October, 1954, complaining that three weeks previously her left arm had become swollen It had remained so for ten days before returning to its normal size When asked whether she had had pain in the chest, she described attacks of pain behind the upper sternum after taking alcohol The first had been at Christmas, 1952, about five minutes after drinking three quarters of a glass of port After a minute or two the pain had become very severe and had been felt round the root of the neck to the back and down both arms, it had waned during about twenty minutes, but soreness persisted until the next day

Between that occasion and her attendance at hospital in October, 1954, she had taken alcohol five times gin twice, sherry once, a very small amount of stout once, and once a teaspoonful of spirits of sal volatile (70% alcohol) Each drink caused an attack of pain identical with the first She remembered having taken sal volatile in April, 1952, when it did not cause pain. Apart from these attacks and the transient swelling of the arm she had been well except that she had lost a few pounds in weight

Examination and Investigations

The patient looked well, the left external jugular vein was prominent and appeared to be thrombosed. There were no clinical signs of a mediastinal tumour no lymph-nodes were palpable, and the liver and spleen were not enlarged.

Radiographs of the chest (fig 1) showed a round poorly defined opacity about 2 cm in diameter in the antero superior mediastinum, tomography did not define it more exactly Blood hæmoglobin 10 6 g per 100 ml (73%), total and differential white cell counts normal, erythrocyte sedimentation rate (Wintrobe) 38 mm in first hour

Administration of alcohol by gastric tube or by vein produced attacks of the pain of which she complained 5 ml of absolute alcohol in 10% solution was given by vein in six minutes Pain started coincidentally with the end of the infusion, and reached a maximum within three minutes It was very severe, and after twenty minutes 100 mg of pethidine was given. On another occasion 5 ml of alcohol in 10% solution was given by gastric tube pain started six minutes after the end of the instillation and lasted for twenty minutes In both of these observations saline solution was given as a control and the patient did not know when alcohol was being administered

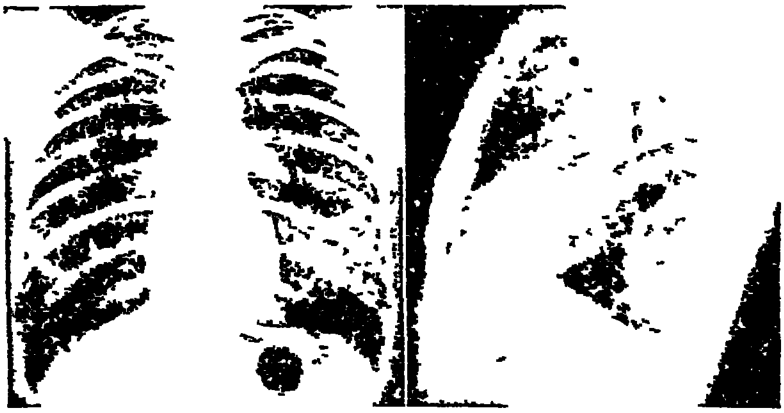

Fig 2—Case 1 Radiographs of chest, May, 1956

Progress

It was decided not to explore the mediastinum because the tumour was presumed to be a manifestation of Hodgkin's disease The patient was therefore advised to avoid alcohol and was discharged from hospital

In February, 1955, having a cold she bought some "cold and influenza mixture" The single dose of this which she took produced an attack of pain like the previous ones except that it was less severe From the composition of this mixture the dose was calculated to have contained about 1 5 ml of absolute alcohol

Apart from this, she remained well In March 1956, a radiograph of the chest showed the tumour to be larger and better defined She was admitted to hospital in May 1956 There was now some dullness behind the upper end of the sternum but no other physical signs Radiography showed bilateral widening of the superior mediastinum, the lateral view showed that the shadow measured 6 4 cm and had an irregular outline, suggesting infiltration (fig 2) Much to our surprise, giving alcohol now caused no pain Under the same controlled conditions as before 20 ml was given by gastric tube The patient had slight discomfort but a similar sensation was sometimes felt after control instillations, she felt no pain then nor did she on another occasion after drinking 80 ml of gin

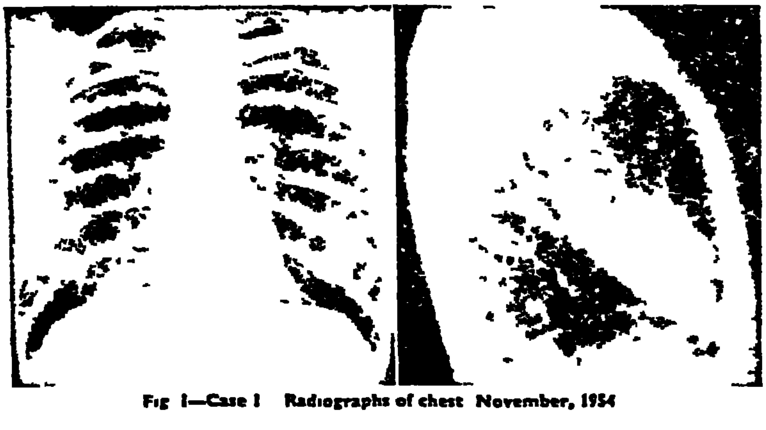

Fig 1—Case 1 Radiographs of chest November, 1954

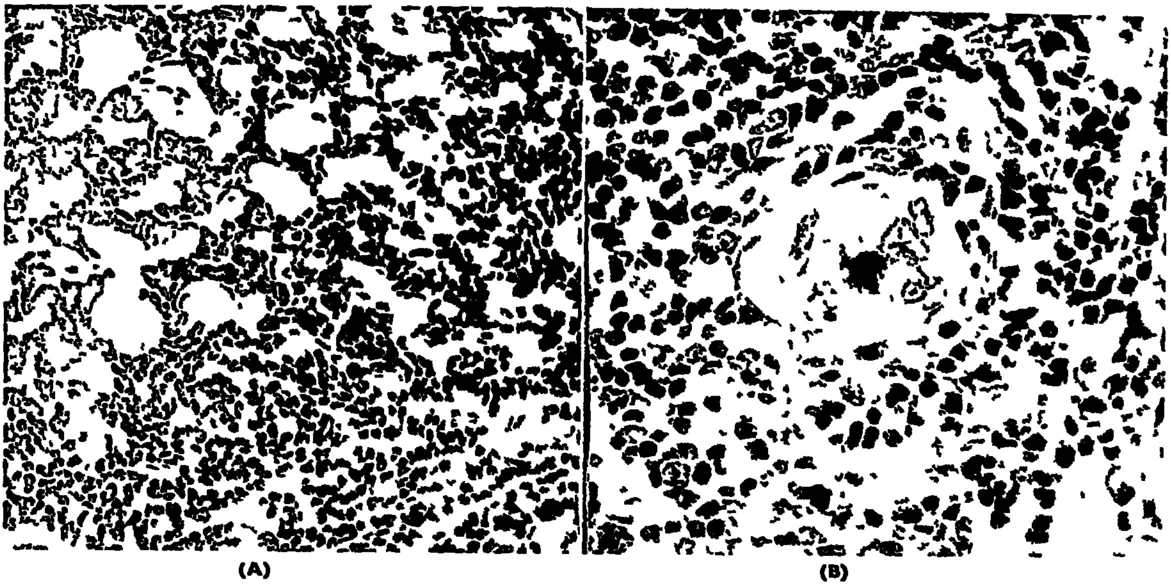

Fig 3—Case 1 Photomicrographs of the tumour A, area showing cribriform pattern with mucoid stroma (Hæmatoxylin and eosin, × 250) B, below abortive Hassall's corpuscle (Hæmatoxylin and eosin × 500)

Operation and Further Progress

It was now decided that the uncertainty about the nature of the tumour justified exploration On May 30, 1956, the sternum was split down to the fourth costal cartilage A hard unencapsulated mass was found infiltrating the front of the pericardium, over an area 2–3 cm in diameter in the region of the roots of the great vessels, as well as the superior mediastinal structures behind the manubrium A globular extension of this mass on each side was invading the anterior margins of the two lungs, more on the right than the left The remaining portions of the lungs, including their hilar regions, were normal When the pericardium was opened a turbid yellow effusion was revealed, and the tumour was seen invading the wall of the pulmonary artery at its junction with the right ventricle The extension of the tumour which had invaded the right lung was resected for histological examination, but the mediastinal part of the mass could not be removed

After her recovery from the operation the patient was given deep X ray therapy to the mediastinum When last seen in October, 1956, she was free of symptoms she has not taken alcohol again

The Tumour

The histological appearances of the tumour varied greatly in the sections examined The tumour consisted in some areas of solid epithelial cords and clusters, and in others exhibited a cribriform pattern composed of slightly elongated ovoid epithelial cells, resembling a bronchial carcinoma (fig 3A), the mucoid stroma in the latter areas gave a positive reaction with the periodic acid/Schiff reagent, whereas staining for amyloid was negative In other areas the tumour was much more pleomorphic, almost mimicking Hodgkin tissue Elsewhere, however, follicular collections of small round cells with abortive Hassall s corpuscles were found (fig 3B) This suggested strongly that the tumour was of thymic origin, as did the appearances at operation

CASE 2 —A married woman, aged 57, was admitted to hospital on Sept 25, 1956 She had felt quite well until eight weeks previously when she noticed aching across the front of her chest, gradually extending to her back, shoulders and upper arms, her whole chest feeling 'stiff and taut" These symptoms persisted and became steadily worse For six weeks she had had a dry cough, there were no other spontaneous complaints, but she admitted a loss of weight of 2 stone in a year

She was a moderate smoker, and had been a moderate drinker until this illness About two weeks after her pain started she noticed that alcohol, which she took in the form of beer, stout, or wine, increased the severity of the pain For four weeks she had preferred to abstain rather than experience the acute exacerbation of pain which alcohol always caused The pain got worse a few minutes after taking the first mouthful, and then gradually diminished, finally disappearing about half an hour later, even though she continued to drink

Examination, Investigations, and Course

The patient was weak, she had evidently lost weight, and she coughed frequently She complained repeatedly of the pain described No abnormal physical signs were detected in any system

She was given 60 ml of 5% alcohol by mouth, in two or three minutes the pain, which before the drink was only slight, became much worse, returning to its original intensity after a quarter of an hour

Radiography of the chest showed a rounded opacity in the left lower lobe, just above the diaphragm, tomography showed this to be lobulated (fig 4) No acid fast bacilli or malignant cells were found in the sputum, and a blood count and a barium meal were normal

Bronchoscopy revealed narrowing of the left main bronchus, which was also rigid, so that the bronchoscope could not be passed more than about 1 cm beyond the carina Several

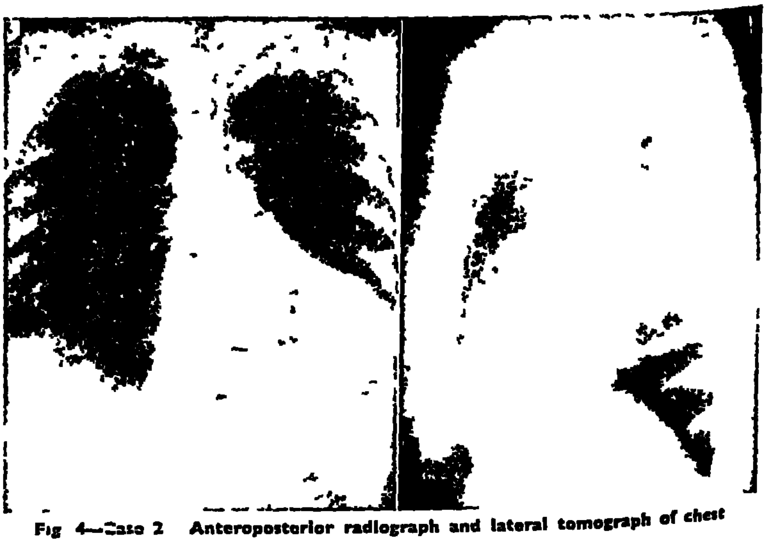

Fig 4—Case 2 Anteroposterior radiograph and lateral tomograph of chest

pedunculated masses were seen, and a specimen was taken for biopsy This was described (Dr R Seal) as showing "a partly necrotic poorly differentiated neoplasm"

The patient's condition deteriorated, and she died thirteen days after admission

Necropsy

At necropsy (Dr B J Stephens) there was a moderate amount of pericardial fluid, and tumour was infiltrating the outer layer of the pericardial sac The left main bronchus was much narrowed by growth infiltrating it from the surrounding tissues, the right main bronchus was narrowed by compression There were several areas of growth in the left lower lobe The pancreas contained a few small areas of growth, and the tail was undergoing necrosis

Microscopy showed, in the pancreas, numerous small areas of pancreatic adenocarcinoma, fairly well differentiated Similar growth was present in the lung, the bronchial mucosa was replaced by a membrane composed of fibrin and partly necrotic carcinoma There was a small deposit of adenocarcinoma in one kidney

Discussion

In case 1 we observed a feature which, so far as we know, has not been described—the spontaneous disappearance of the liability to alcohol-induced pain, at a time when the patient had not had any treatment and the tumour was enlarging There was an interval of just over a year between the last time she had the pain (due to alcohol in influenza mixture) and the finding that pain could no longer be produced We therefore do not know whether the disappearance, which we cannot explain, was sudden or gradual

Before concluding that this rare symptom may very occasionally be produced by any type of malignant tissue, we make two reservations

In case 1 the tumour was probably of thymic origin Thomson (1955) has suggested that Hodgkin's disease is a disseminated carcinoma of which the primary growth is in the thymus, alcohol-induced pain in a patient with a thymic carcinoma might be held to support this hypothesis

The second patient had an adenocarcinoma, probably of pancreatic origin Alcoholism is among the recognised causes of acute pancreatitis, but as a rule the association between drinking and pain is much more remote in time than it was in the patients we have described But in two patients in the series described by Joske (1955) the pain was immediate, and was compared by him to the alcohol induced pain of Hodgkin's disease The mechanism by which alcohol causes such pain in pancreatitis is unknown, but it will be remembered that necrosis was found in the tail of the pancreas in our case 2, and that much of the growth in the chest was necrotic

In neither of our cases was there any evidence of involvement of bone Alcohol-induced pain has been described in two patients with suppurative lesions of bone (Alexander 1953), and one of us has had this symptom at the site of chronic osteomyelitis Infiltration of bone is not essential to the production of alcohol-induced pain in Hodgkin's disease, in several of the reported cases, the patient had such pain at the site of soft-tissue lesions

With these reservations, our experiences suggest that alcohol induced pain is not specific to Hodgkin's disease but that it may occur in other malignant conditions, and that it may be the first indication of their presence Had we known this, case 1 might have been explored while the tumour was still removable Until more is known about this odd symptom it should be systematically inquired for (since it is not always mentioned spontaneously), and it should not be assumed to be diagnostic of Hodgkin's disease

Summary

Two cases of alcohol-induced pain associated with carcinoma, probably of thymus and pancreas, are reported

In one the symptom disappeared spontaneously although the tumour was enlarging

We thank Dr M I Jackson for referring case 2, colleagues named in the text for their help, and Prof Harold Scarborough and Dr Paul Fourman for constructive criticism

ACUTE PORPHYRIA IN PREGNANCY

R TUDOR HUGHES
M B Lond
MEDICAL REGISTRAR, WREXHAM HOSPITALS, DENBIGHSHIRE, WALES

THE manifestations of acute porphyria are widely known, and hundreds of cases have been published, but few reports have appeared of acute porphyria associated with pregnancy, and the conclusions reached in these reports on the influence of porphyria on pregnancy and on the effects of pregnancy on established cases of porphyria are in some ways contradictory The case described here introduces some problems in the management of acute porphyria during pregnancy

Case-report

A housewife, aged 19, was admitted on June 13, 1955, with two days' history of hypogastric pain and early morning vomiting She had been married three months, and her last menstrual period was on March 26, 1955, but she had slight vaginal bleeding five weeks before admission She had been admitted to hospital in November, 1953, with hypogastric pain and diagnosed as having primary dysmenorrhœa, and in March, 1955, with anorexia, colicky lower abdominal pain, and vomiting after meals Her parents were not related, and there was no history of porphyria in the family

On admission she presented no abnormal physical signs, and her general condition was good

Treatment and Progress

For the next week she complained of severe backache and pains in the legs, and during this time she received pentobarbitone sodium ('Nembutal') gr. 1½ on five occasions Slight conjunctival icterus was noted and infective hepatitis suspected She was miserable and uncoöperative and had diffuse abdominal tenderness but no rigidity On June 21, 1955, her urine was of the classical "port-wine" colour Her abdomen was tender on palpation Her limb muscles were tender, but her reflexes were present, and she had no sensory loss Acute porphyria was diagnosed, and the diagnosis was confirmed by finding 127 mg of porphobilinogen per litre of urine Barbiturates were forbidden from then on

The generalised pain and muscle tenderness continued So treatment was begun with subcutaneous neostigmine 0 5 mg six-hourly initially, the dosage being increased daily until a maximum of 4 mg six hourly was reached Pethidine was used to relieve pain with good effect The polyneuritis however, did not remit, and by July 1, 1955, there were obvious abnormal physical signs in the central nervous system weakness of the arms and legs with wasting, especially in the biceps and triceps, quadriceps, and calf muscles, impairment of sensation to pinprick over the front of the thighs and legs lack of tendon reflexes in the arms, right knee jerk and abdominal reflexes, flexor plantar responses, and narrowed calibre of the retinal arteries

After two weeks administration neostigmine was withheld because of signs of intolerance, particularly diarrhœa and sweating Neostigmine did not appear to influence the illness Treatment with tolazoline hydrochloride ('Priscol') 25 mg t d s was started but stopped because of persistent vomiting

Weakness of the intercostal muscles and difficulty in swallowing were evident on July 12, 1955 and the patient was nursed from then on in a ward reserved for cases of bulbar poliomyelitis and providing facilities for suction and intermittent positive pressure respiration Feeding by intragastric drip was necessary partly because of the dysphagia and partly because of the total lack of cooperation by the patient, who remained miserable and depressed Generalised pains were constant and were relieved only by frequent doses of pethidine So subcutaneous pentolinium tartrate ('Ansolysen') 1 mg twelve hourly was given initially, the dosage being increased until 12 5 mg eight hourly was being given, the blood-pressure was measured frequently During this treatment the patient had severe constipation and retention of urine, which were relieved by oral neostigmine 15 mg t d s

Movement of the legs improved by July 14, 1955, and swallowing became easier, but the *patient's mental attitude* remained the same, and she vomited frequently Her blood-pressure fluctuated considerably, there being a tendency to hypertension, the pressure ranged from 120/80 to 150/110 mm Hg according to the dosage of pentolinium

In August, 1955, it became obvious that the patient was pregnant, she still tended to vomit and complained of pains in her back and limbs, whose movements improved a little The pregnancy progressed favourably, but often the presence of severe hypogastric pain suggested premature labour Frequent use of pethidine and amidone effectively relieved the pain After neostigmine was withheld on Oct 6, 1955, there was no more retention of urine Improvement continued until early December, 1955, when the severe pain recurred and the mental attitude deteriorated badly

Delivery and Death

On Dec 13, 1955, labour came on rather suddenly, and a live female infant, only mildly asphyxiated, was born There was a hæmorrhage of about 15 oz during the third stage of labour Injection of ergometrine 0 5 mg and massage of the fundus controlled bleeding After delivery the patient's blood-pressure was 130/115 mm Hg and pulse rate 160 The patient's mental attitude changed profoundly depression gave way to extraordinary cheerfulness Her general condition was poor, she was dehydrated, and her high pulse rate suggested that intravenous fluids and blood were necessary She was vomiting small quantities of brown watery fluid After the blood transfusion was started her pulse rate rose to 186 and blood pressure began to fall She became pulseless and died seven and a half hours after the birth of the infant The infant died a few hours after delivery

Investigations

Examination of the *blood* revealed toxic granules in the polymorphs but no other abnormality *Liver function tests* on June 22, 1955, serum bilirubin 0 2 mg per 100 ml (direct 0, indirect 0 2 mg per 100 ml) and thymol turbidity 3 units, on July 13, 1935, serum proteins 7 g per 100 ml, serum alkaline phosphatase 6 units (King), thymol turbidity 4 units, and thymol flocculation 14 units The *urine* occasionally contained traces of albumin, leucocytes, and erythrocytes It fluoresced under ultraviolet irradiation On June 24, 1955, it contained porphobilinogen 127 mg per litre, and on Sept 13, 1955, 80 mg per litre *Electrocardiograms* were normal The *skin* did not fluoresce under ultraviolet irradiation The patient said that, for as long as she could remember, she had blistered very easily in sunlight, but there was no evidence of scarring as a result of this

Necropsy Findings

Permission was obtained for only a limited necropsy The thoracic and abdominal organs appeared normal on both macroscopical and microscopical examination No abnormality was found in the baby

Effects of Drugs

Pethidine was used frequently and with good effect in the relief of pain in the dosage of 100 mg intramuscularly every four to six hours

Neostigmine was given intramuscularly from June 24, 1955, to July 7, 1955, 0 5 mg six hourly initially and increased to 4 mg six-hourly It was withheld because of diarrhœa, sweating, and dryness of the throat

Given orally in the dosage of 7 5 mg t d s from July 18, 1933, to Oct 6, 1955, it relieved constipation and retention of urine (possibly caused or aggravated by pentolinium) but did not influence the pain or the peripheral neuritis After neostigmine was withheld on Oct 6, 1935, bowel and bladder function were normal

Tolazoline given orally from July 7 to 12, 1955, in the dosage of 25–50 mg t d s was not well tolerated and did not appear to influence the course of the disease It produced persistent vomiting

Pentolinium tartrate—'Ansolysen Retard' was given subcutaneously from July 12, 1955, to Aug 19, 1955, in the dosage of 1 mg eight hourly initially and increasing gradually to 12 5 mg eight hourly The dosage was frequently adjusted to control the rise in blood pressure It did not appear to alleviate the pain, and we were not impressed by its effect

Vitamin B_{12} ('*Cytamen*') was given intramuscularly in dosages of 100–1000 µg daily from Aug 12, 1955, to Sept 20, 1955 Its administration coincided with slight subjective improvement and disappearance of muscle tenderness

Chlorpromazine given orally in the dosage of 25 mg t d s from Aug 22 to Aug 29, 1955, produced no effect

Vitamin B concentrate, vitamin A, and *vitamin D* were also given in full dosages as a routine

Discussion

This case illustrates most of the classical features of acute porphyria This attack appears to have begun in early pregnancy Although there was some improvement in the later months, severe deterioration took place a few days before labour, and the patient died in a state of shock seven and a half hours after the delivery and after having half a pint of blood transfused

Influence of Pregnancy

The influence of pregnancy on acute and chronic porphyria has been commented on in a few published reports

Dean (1953) stated that during pregnancy the patient was usually much worse, and suggested that this might be due to sedatives In the present case the porphyria had presumably developed before admission to hospital, after which barbiturates were given on four occasions before the diagnosis was established

O'Dwyer (1955) suggests that pregnancy may benefit patients with porphyria by stimulating the endocrine system and reports a twin pregnancy in which the patient improved after delivery The improvement, however, did not take place before the end of the pregnancy, so one might argue that his patient benefited more from the return to the non pregnant state

Rawlings (1950) noted improvement during pregnancy Coleman (1948) reported a case in which pregnancy was well tolerated and delivery was by cæsarean section

The case described by Freedman et al (1952) was of great severity and of particular interest because the patient became pregnant in a remission of her ten months' illness Her porphyria was exacerbated in the first trimester but subsequently improved It seems that the pregnancy precipitated a further attack of porphyria

In the present case the pregnancy seemed to precipitate the first major attack of porphyria, but the previous episodes of "primary dysmenorrhœa" and "pelvic congestion" were probably minor episodes of porphyria The number of cases published is too small to show with certainty the effect of pregnancy on acute porphyria but is, I think, sufficient to advise caution in permitting pregnancy in women known to have porphyria It seems clear, however, that pregnancy can proceed normally in cases of acute porphyria, in spite of the clinical deterioration of the patient

Blood transfusion

The fact that the patient died shortly after a blood transfusion may be significant There was nothing to suggest an incompatible transfusion, and one wonders whether transfusion of blood in such a profound metabolic disturbance is advisable Coleman (1948) reported a case in which a blood transfusion was given without untoward reaction, and Freedman et al (1952) noted improvement after a blood-transfusion Possibly in the present case the serious deterioration after the blood transfusion was coincidental

Ergometrine

The use of ergometrine after delivery of the placenta may have been a factor causing the early postnatal deterioration The manifestations of acute porphyria are thought to be due to vasospasm causing foci of ischæmic necrosis, porphyrins being vasoconstrictors It is probably unwise to potentiate this action by using drugs such as ergometrine

A change in mental attitude after delivery has been noted by Freedman et al (1952), whose patient underwent complete change of personality

Summary

A case of acute porphyria in pregnancy is described

Blood-transfusion and ergometrine are suggested as factors that may have caused death

I wish to thank Dr P R C Evans for advice and encouragement in the preparation of this report, and Prof C Rimington for help in investigating the case

FATAL AGRANULOCYTOSIS DURING CARBIMAZOLE THERAPY

G B TAIT
M D Edin, M R C P E
PHYSICIAN, DEWSBURY, BATLEY, AND MIRFIELD HOSPITAL GROUP, YORKS

CARBIMAZOLE appears to be one of the least toxic of anti thyroid drugs In a review of published reports Burrell et al (1956) found an incidence of major toxic effects of 0 5% By "major toxic" effects they meant either serious depression of the marrow or drug fever (with or without enlargement of lymph glands), or arthralgia They found that agranulocytosis had been reported in only 4 cases in the United Kingdom and the United States The toxic symptoms came on within two months of the start of treatment with carbimazole and developed only with a dosage of more than 20 mg daily

Burrell (1956) lists 6 published cases of serious depression of the marrow and adds 1 further case, which was fatal Of the 6 cases 1 was fatal (Richardson et al 1954)

Of the 21 cases I have treated with carbimazole, 2 have shown depression of the polymorphs in the peripheral blood, necessitating a change to other treatment (perchlorate) A third patient developed complete agranulocytosis and died In view of the widespread use of carbimazole and its apparent low toxicity, I record this last case

Case-report

A man, aged 66, was admitted to hospital on April 30, 1956 He stated that he had been well until about a fortnight previously, when he developed what was probably an infection of his upper respiratory tract When he got better from this he did not recover his usual energy and he became short of breath on walking This dyspnœa soon became persistent being greatly aggravated by any attempt to lie down Palpitations began to trouble him Swelling of the feet and ankles appeared about a week after admission to hospital

His previous health had been good, apart from a recurrent cough each winter and a "large neck" for very many years The family history was not relevant

Examination —On admission he was dyspnœic and had engorged neck veins and moderate œdema of his feet and legs The isthmus and the right lobe of his thyroid gland were enlarged and the right lobe was nodular His pulse rate was 150, the pulse being irregular in rhythm and force His heart was enlarged to the left with the apex beat $^1/_2$ in outside the left mid clavicular line At the apex was heard a harsh systolic bruit which was not propagated in any particular direction His blood pressure was 180/80 mm Hg His prostate gland was enlarged

He was regarded as having left ventricular failure with atrial fibrillation due to hyperthyroidism from a nodular goitre

Investigations —Radiography showed an enlarged heart with pulmonary congestion and small bilateral pleural effusions The hæmoglobin was 84% and the white cell count 6000 per c mm (neutrophils 66%, eosinophils 1%, basophils 2%, lymphocytes 21%, monocytes 10%) The blood-cholesterol was 90 mg per 100 ml The urine was infected with coliform bacilli sensitive to chlortetracycline (aureomycin)

Treatment was begun with chlortetracycline 250 mg six-hourly for eight days and digoxin 1 0 mg initially, followed by 0 5 mg six-hourly till digitalised, followed by a maintenance dose A test dose of 0 5 ml of intramuscular mersalyl was given, after which the patient collapsed and his pulse rate rose alarmingly This was regarded as a toxic reaction to mersalyl, and no more was given Carbimazole 10 mg three times a day was administered from the start

Progress —The patient's urinary-tract infection persisted, and culture on May 14 grew coagulase positive *Staphylococcus aureus* sensitive to nitrofurantoin ('Furadantin') During this period the white cell counts showed a neutrophil leucocytosis of 21,650 per c mm on May 11 to 15,000 per c mm on May 19 With nitrofurantoin therapy the urine became sterile on May 24 On May 29 the white cell count was 15,000 per c mm (neutrophil polymorphs 8000 per c mm) By this time the patient was much improved as regards urinary symptoms, cardiac failure, and hyperthyroidism, but on June 7 the white cell count was 7000 per c mm (neutrophils 4550 per c mm) On the 19th his temperature rose suddenly, and he looked ill His throat was healthy Carbimazole was stopped immediately A white cell count showed 300 per c mm (neutrophils 6 per c mm) The hæmoglobin was 62% Treatment with penicillin and blood-transfusion was started, but the patient deteriorated rapidly and died on June 22 Before death his urine again contained coagulase positive *Staph aureus*

Necropsy revealed an enlarged prostate cystitis, and a nodular goitre The heart was considerably enlarged

Comment

This patient developed fatal agranulocytosis while on carbimazole 30 mg daily So far as I am aware, no depression of the marrow has been reported to follow use of treatment with nitrofurantoin, so it seems clear that the carbimazole was responsible The patient developed what was probably a reaction to mersalyl, and this suggests that he may have been predisposed to drug reactions, although he gave no previous history of allergy Most cases of neutropenia recover when the offending drug is withheld, as in the two previous cases, in which, however, the neutropenia was never severe and the patients were never ill These 2 cases were detected by routine white cell counts, which most authorities today regard as of little value Though agranulocytosis usually comes on with dramatic suddenness, occasionally there is a more gradual depression of neutrophils This suggests that the routine white-cell count is not altogether valueless during the first two months of therapy

Summary

A case of fatal agranulocytosis in a man, aged 66, treated with carbimazole is described

This appears to be the eighth recorded case of severe hæmatological reaction to carbimazole, and the third fatal case

Two other cases of neutropenia detected by routine white cell counts are mentioned

repeated renal circulatory damage was additive in its effects on kidney function Oliguria and anuria due to polyarteritis nodosa or acute glomerulonephritis was of more serious prognosis than the more usual cases of acute tubular necrosis and did not appear to be benefited by cortisone

Of tubular lesions, acute tubular necrosis due to renal ischæmia and proximal tubular necrosis due to nephrotoxic drugs had a more favourable prognosis than renal cortical necrosis with simultaneous glomerular damage and renal papillary necrosis affecting the renal papillæ and collecting tubules Obstructive lesions of the ureters should be treated surgically but were important to the physician since they could mimic medical varieties of anuria Conservative treatment was essential in all cases of acute renal failure, but dialysis with the artificial kidney was useful in cases showing uncontrolled hyperkalæmia or acidosis

Dr A M JOEKES described some illustrative cases of oliguric renal failure complicating medical conditions One cause of acute tubular necrosis which had not often been recognised was the profound circulatory collapse after a major pulmonary embolism Hepatic disease with jaundice seemed to predispose to acute renal failure Dr Joekes described 4 cases associated with biliary cirrhosis and acute hepatitis, all 4 recovering from the episode of renal failure The rôle of hæmoglobinuria in the production of acute tubular necrosis was still undefined While renal damage was common after incompatible blood-transfusion and in blackwater fever, it was rare in acute hæmolytic anæmia An additional element of circulatory shock seemed to be an essential factor in causing renal damage

Percutaneous renal biopsy was sometimes of great value in assessing whether recovery was possible, and therefore in guiding therapy In a case of scleroderma with severe renal damage, prolonged conservative therapy had been deemed undesirable in view of the gross and irreversible renal damage found at biopsy

Dr E M DARMADY described the changes in acute tubular necrosis as shown by microdissection of nephrons and histological preparations Immediately after the onset stage the glomeruli were engorged with blood, and this was followed by a focal loss of translucency of the tubules, mostly confined to the proximal segment In the early stage of anuria or oliguria, transparent casts were seen in the lower end of the proximal tubule and loops of Henle, there was scattered tubular epithelial disarrangement and focal necrosis In the middle of the anuric phase there were tubular ruptures in all parts of the nephron, at the same time there were prominent casts in the distal and collecting tubules In the diuretic phase there was evidence of epithelial regeneration in the previously damaged portion of the nephron Dr Darmady considered that interstitial œdema with increase of intrarenal pressure was not the cause of the oliguria Since many of the tubules were not sufficiently damaged to prevent urinary secretion it was thought the glomeruli must be the operative factor in causing the anuria or oliguria Possibly the engorgement of the glomeruli in the early stages was similar to the anuria occurring in homotransplanted kidneys in dogs, for, although there was damage to the juxtaglomerular portion of the nephron which could be partly prevented by cortisone, injection of indian ink into the renal circulation at the time of anuria showed that the glomeruli were overfilled with blood, suggesting lack of tone of the capillary tuft with a sluggish circulation

In the recovery phase of oliguria there might be considerable excess urinary potassium loss In these cases the tubular cells showed the typical " vacuolar nephropathy " of potassium depletion—a change which Dr Darmady had also found in kidneys from cases of primary aldosteronism

Reviews of Books

Pediatrics

Edited by DONALD PATERSON, M D , formerly clinical professor, department of pædiatrics, University of British Columbia , JOHN FERGUSON McCREARY, M D , professor and head, department of pædiatrics, University of British Columbia Montreal J B Lippincott, London Pitman Medical Publishing 1956 Pp 654 £3 10s

THIS new Canadian textbook is edited by Dr Paterson, whose books on infant feeding and diseases of children became well known in this country when he practised in London, and by Dr McCreary, who crossed the American continent a few years ago from Toronto to become professor of pædiatrics in the new medical school at Vancouver Of the 36 contributors, 21 belong to that school and 7 to Toronto, while 7 other Canadian medical schools are represented

Canadian practitioners felt the need for a book of medium size such as this, with a practical approach and emphasis on diagnosis and treatment and the common problems of pædiatric practice Rarities are mentioned briefly, thus ensuring a well-balanced comprehensive picture The work includes chapters on *accidents* and sudden death , diseases of the ear, nose, and throat, eyes, skin, and bones and joints , disturbances of adolescence , and pædiatric gynæcology It is well arranged and concisely written and the illustrations are good, though more than 102 would have been welcome in such a good volume

Chemosurgery in Cancer, Gangrene and Infections

FREDERIC E MOHS, B SC , M D , associate professor of chemosurgery, department of surgery, University of Wisconsin Medical School Springfield Charles C Thomas, Oxford Blackwell Scientific Publications 1956 Pp 305 102*s* 6*d*

Too little thought has been given to the possibility of destroying surface growths by chemical means Dr Mohs has devised a system whereby such lesions may be eliminated by using zinc chloride, which penetrates and " fixes " the mass After one application the fixed mass is removed and examined histologically , should malignant cells be seen on the deep surface, zinc-chloride paste is again applied to the area , several applications may be necessary Surgical excision can be undertaken initially and followed by chemical treatment The method calls for experienced histological control , the five-year-survival figures indicate that in Dr Mohs's hands chemosurgery compares well with other methods

An Introduction to Electrocardiography

L SCHAMROTH, M R C P E , F R F P S , University of Witwatersrand and General Hospital, Johannesburg Cape Town and Johannesburg Juta 1956 Pp 60 21*s*

IN this short book the essential principles of electrocardiography are clearly explained on a basis of simplified electrophysiology The text is illustrated by diagrams which are mostly helpful , but the value of this introduction would have been enhanced by the inclusion of some typical electrocardiograms diagrams, however good, are indifferent substitutes As it is, the book should be a most useful supplement to larger textbooks of electrocardiography

Traité des urgences en chirurgie

Vols 1 and 2 P BROCQ, F POILLEUX, R CHABBUT Paris Masson 1956 Pp 1301 Fr 8000

THIS comprehensive work on emergency surgery is designed to cover all contingencies which might be encountered by an isolated surgeon working in a remote area , fractures are therefore very properly included It is an instructional work with a didactic flavour Though in some respects practice differs from that in this country, there is a general concurrence of view

---

Child Development (London Tavistock Publications 1956 Vol 2 Pp 271 28*s*)—The proceedings of the second meeting of the World Health Organisation study group on the psychobiological development of the child, held in London in 1954, have been published under the editorship of Dr J M Tanner and Prof Barbel Inhelder

THE LANCET

LONDON SATURDAY, FEB 9, 1957

Cancer of the Œsophagus

TWENTY years ago the œsophagus was a surgical no man's land separating the laryngologist from the abdominal surgeon—and both approached it with trepidation The results of surgery for malignant disease of the œsophagus were very poor, and the best that could be said for radiotherapy was that it often precipitated the end by causing a perforation of the œsophagus The picture has changed The opportunities offered by advances in anæsthesia, by the new antibiotics, and by a more physiological approach to postoperative care have been seized with enthusiasm by the surgeon[1], and super-voltage machines have enormously increased the power and range of radiotherapy So impressive are these new methods of treatment, and so many are the alternatives suggested for different types of growth and patient, that, if steady progress is to be achieved, their relative merits must now be carefully weighed SMITHERS[2] rightly insists that, restricted though its use may be to a few centres, modern radiotherapy (like modern surgery) should be judged by the best it can offer, and, reviewing 314 cases of cancer of the œsophagus, seen at the Royal Marsden Hospital between 1936 and 1951, he is in an excellent position to form such a judgment 65 patients in this carefully analysed series are grouped as "untreated", but they include those who had such minor palliative procedures as the passage of Souttar's tubes, gastrostomy, or jejunostomy None survived for two years, and 95% were dead within six months These dismal figures closely agree with the recently published findings of MUSTARD and IBBERSON[3] from the Toronto General Hospital and they confirm the low opinion in which gastrostomy and jejunostomy are generally held Both operations shorten rather than prolong life inflict rather than alleviate suffering This is the grim background against which all the bolder forms of treatment must be evaluated

In the Royal Marsden Hospital series 20 of the 314 patients had the growth resected 5 of them survived for two years and 1 of them is still alive after eight years In the Toronto series (381 cases seen by various members of the General Hospital staff in the years 1947–53) the tumour was operated on in 133 patients and resection was possible in 100 Of these 133, 48 died before they left hospital but 7 survived for five years or more SMITHERS also describes the results in 229 patients treated by radiotherapy 20 survived for two years and 7 for five years (Of these 7 patients 4 eventually died of unrelated intercurrent disease but 2 succumbed to late recurrence of cancer) The Canadian results in 55 irradiated patients show 10 two-year survivals and 1 five-year survival Such figures are, of course meaningless, if not actually misleading, unless note is taken of the many things which influence the selection of patients and, indeed, a consideration of these is in some ways more illuminating than a contemplation of the numerical end-results The most notorious variable in internal selection is the anatomical definition of the œsophagus, and its bearing on statistical findings, especially those relating to cancer, is well illustrated by the Canadian series This group includes among tumours of the upper third of the œsophagus, cancers of the laryngo-pharynx, a type of growth which differs from more distal growths in its age and sex incidence (it predominantly affects middle-aged women), as well as in its accessibility and response to treatment Perhaps because of the "almost infinitely repeated trauma of the food bolus squeezing through the crico-pharyngeal sphincter,"[3] malignant disease is very common in this short segment of the alimentary tract, and no less than 27% of all "œsophageal" tumours in the Toronto series started in this region At the lower end of the gullet it was impossible to exclude with complete certainty all cancers arising from the stomach, and though every effort was made to do so, it is perhaps significant that both the long survivors with lesions of the abdominal œsophagus had adenocarcinomas Other variables, such as standards of skill, differences in the personal experience of the surgeon or radiotherapist, and the closeness of the coöperation between them, make it hard to compare results from different sources Nevertheless, such comparisons are one of the few sources of guidance for the future, true results are, after all, only beginnings

It is often said that by and large, modern radiotherapy and surgery achieve similar results in carcinoma of the œsophagus Such remarks reveal a tendency to stray prematurely to the foot of the column marked "total" rather than examine the data in full, for all surgical series contain a preponderance of lower-third tumours, accounting sometimes for as many as 50% or 60%,[4 5] and disproportionately few upper-third cancers In groups of patients treated by radiotherapy, though results for all sites may be inferior, the growths are usually more evenly distributed[2 6 7] At least one reason is not far to seek surgery is undoubtedly at its best in the lower reaches of the œsophagus, and least successful near the upper end Radiotherapy, on the other hand, has proved most effective in the upper œsophagus (whence metastases to subdiaphragmatic lymph-nodes are late and uncommon)

There is even less justification for saying that today's five-year survivals reflect only the natural history of the disease Gloomy as the prognosis of œsophageal cancer still is treatment has certainly restored health to a few patients, prolonged life in some, and made existence tolerable for many Surgery can do much in the way of palliation and it could do more if surgeons were less reluctant to admit that the chances of absolute cure—even in the best

hands—are still remote, and that the best radical operations are not always the best palliative ones Now that a sound palliative operation can ensure several months, or even years, of comparative comfort, it is self-deception to say after an unsatisfactory resection and anastomosis (often a patched-up affair at the end of a gruelling three-hour session) that it will at least relieve the patient of his discomfort Should the patient survive (and his chance is hardly better than even) he would have been better served with no resection, and, what is more disturbing, nine times out of ten this has been plain from the beginning "On passe souvent de l'amour à l'ambition, mais on ne passe guère de l'ambition à l'amour"[8] it is a sad paradox that the number of different radical operations recommended (and presumably practised) today almost certainly exceeds their total number of survivors Even those that look sound on paper should be judged with at least one eye on the mortality figures—which are sobering **Humphreys** and **Moore**[9] report from the Presbyterian Hospital in New York that of all patients seen there with primary œsophageal cancer (162 cases in ten years) there was not 1 five-year survivor At the New Haven Hospital, during a similar period, the only 3 survivors had adenocarcinomas, probably originating in the stomach[10] **Parker** and **Jenkins**[11] could find only 1 five-year cure at the Roper Hospital, Charleston, in a review of 210 cases, and **Ravitch**,[12] though he does not give the total number of patients that were seen, could find none at the Johns Hopkins Hospital There may be scope for improvements in operative technique, but neither its present imperfections nor delay in diagnosis can take much blame for these results In contrast to radical operations, **Mustard** and **Ibberson** are convinced that palliative by-pass operations have real merit and that they are usually feasible "The ability to swallow is promptly restored and maintained regardless of whether or not the primary lesion can subsequently be successfully dealt with"[3] At present **Mustard** and **Ibberson** perform an anterior mediastinal by-pass, using a jejunal Roux loop[13] or a colonic segment, in all "good-risk" patients with malignant obstruction As an alternative, a palliative intubation[14] has the merit of simplicity, and it can be used for growths at all levels

An understandable distaste for compromise may partly explain why radiotherapy (by tradition, if not in fact, palliation par excellence) still rarely gets the consideration it deserves Despite a cure-rate of 7% for tumours of the upper third, **Aird**[15] feels that deep therapy has little to offer for œsophageal carcinoma and though "in the middle œsophagus a fairly effective tumour dose can be obtained by rotating the patient in the beam results are not satisfactory, and in the lower part of the œsophagus this form of treatment is entirely useless" No one will dispute these statements but will they not encourage the less experienced to discard a method which has proved useful, within its limitations, in favour of one which is more spectacular but more lethal? As an alternative to survival-rates of less than 1% after radical surgery in the mid œsophagus (and an almost prohibitive operative mortality), radiotherapy can usually restore the patient's ability to swallow, "with a minimum of discomfort, with a stay in hospital of a few weeks and with virtually no treatment mortality the majority of those patients swallow well until their death"[3] There may or may not be a place for combined therapy —either by preoperative irradiation or the use of radioactive-gold-grain implants[16]—but there is certainly a place for combined efforts in selecting cases for whichever form of treatment holds out most promise **Smithers** believes that "both methods are likely to improve still further in the next few years and they have their individual sites of maximum advantage, but competition to the patient's disadvantage instead of cooperation to produce the best results is still far too common" In the treatment of cancer of the œsophagus, no less than elsewhere, isolated surgical successes, however Homeric in their dash and brilliance, do not justify the Homeric afterthought that "the rest were vulgar death unknown to fame"[17]

New Drugs, Old Dangers

Among the many new drugs that have lately been introduced, the most prominently displayed are the organic chemicals for the relief of pain and insomnia, and the so-called "tranquillisers" The chemical structure of many of these drugs raises suspicion that they may damage the blood-forming tissues and the blood-vessels, and evidence is accumulating to show that this suspicion is justified The chances that a given drug will harm a particular patient are probably very small, and the mounting record of blood disorders may be largely a reflection of the great number of patients who are now being given these drugs, rather than a sign of serious toxicity Nevertheless, there is good reason to emphasise again that many of these substances can kill and that others may yet turn out to be potentially lethal We review below some of the examples of drug-induced blood disorders that have come to notice in the past two or three years

Phenylbutazone ('Butazolidine') was introduced for the treatment of rheumatoid arthritis and other painful joint conditions **Leonard**,[18] who reviewed the literature in 1953, collected 356 instances of toxic reactions among 1526 treated patients, and these included 11 cases of agranulocytosis He himself recorded 1 patient who had fatal aplastic anæmia and 1 who had granulocytopenia but recovered. This second patient had been treated for six weeks when sore throat and fever began, the white cell count was 1600 per c mm with 34% polymorphs, he was treated with penicillin and recovered **Dilling**[19] also described a fatal agranulocytosis due to sensitivity to phenylbutazone This patient had 600 mg daily for five days, but when œdema developed the drug was stopped, after seven days treatment was resumed and 450 mg was given daily Three days later she had severe symptoms, the white-cell count was 2000 per c mm, no polymorphs were found, and the patient died three

days later Another fatal agranulocytosis[20] was the outcome of the patient's insistence on "the new treatment" for her rather vague arthritis After 200 mg daily for four weeks she had sore throat and pyrexia Her white cells numbered 1000 per c mm, with 2% polymorphs, but her marrow still contained 43% myelocytes The white count recovered with treatment, but the patient died, and at the post-mortem examination there were multiple abscesses in the lungs and a few in the liver

Chlorpromazine ('Largactil') is enjoying some popularity as a short-term sedative, and psychiatrists are giving it for longer periods In 1955, Tasker[21] described fatal agranulocytosis in a woman who was being treated for hysteria It is interesting that warning signs appeared when the treatment was begun—pyrexia, slight jaundice, and an irritant rash—but they settled down and treatment was continued for forty-one days to a total of 5 5 g of chlorpromazine Typical acute agranulocytosis, with ulcerative stomatitis then followed, the white count was only 900 per c mm, with 10% polymorphs, and the patient died eight days later Adams et al[22] saw agranulocytosis in a patient in an anxiety state who had been given 12 g of chlorpromazine in eight weeks The onset was sudden with severe pharyngitis and a temperature of 102°F The white cells were down to 800 per c mm, all lymphocytes, and the bone-marrow was almost completely devoid of granulocytes, though erythroblasts and megakaryocytes were present in normal numbers Cortisone and antibiotics were given, and he recovered in a week Another patient was detected at the granulocytopenia stage when she had 1200 white cells per c mm and 34% polymorphs, and she recovered quickly when the chlorpromazine was stopped Schick and Virks[23] have lately collected 21 published cases of agranulocytosis due to chlorpromazine, 8 of them fatal Their own patient had had 100 mg daily for six weeks when the signs and symptoms of acute agranulocytosis appeared, there were 800 white cells per c mm and no polymorphs, the marrow contained only 0 5% myelocytes and no other granulocytes, but normoblasts were plentiful With blood-transfusion, penicillin, and ascorbic acid, the patient recovered in four days

One of the tranquillisers, *meprobamate* ('Miltown,' 'Equanil') has been blamed for purpuric reactions Carmel and Dannenberg[24] saw 3 patients in whom non-thrombocytopenic purpura developed after relatively small doses For example, a woman of 42 was given meprobamate after a minor operation, after 3 tablets of 400 mg purpura appeared over the thigh, trunk, abdomen, and arms, she also had anorexia and fever The platelet-count and other blood examinations were normal, but capillary fragility was increased The purpura subsided in a week Similar purpuric rashes have been reported[25 26] after small doses of meprobamate So far no case of agranulocytosis has been attributed to meprobamate, but 'Pacatal,' another tranquilliser, has been associated with this syndrome Acute agranulocytosis developed after six weeks' treatment with pacatal for depression[27] After 5 5 g had been given, the white count was 3000 per c mm with 53% polymorphs, but nine days later the patient had a sore throat and fever, and the white count fell to 850, polymorphs being completely absent Treated with sodium pentosenucleotide, penicillin, and streptomycin, she recovered in a few days

Another sedative that can cause trouble is *carbromal* It is on sale to the public without restriction and is contained in various proprietary sedatives, such as 'Adalin,' 'Persomnin,' 'Dormiprin,' and 'Somnitil' Borrie[28] described 6 cases of widespread non-thrombocytopenic purpura in patients who had had this drug

Many doctors may be surprised to know that some sedative mixtures still contain the first drug to be implicated as a cause of agranulocytosis, *amidopyrine*, or its derivatives, 'Novalgin' is an example, and it is still causing agranulocytosis from time to time[29 30] There is no virtue (and some danger) in amidopyrine combinations and their use should cease

A quite different drug that is now coming in for criticism is *carbimazole* ('Neo-mercazole'), used in the treatment of hyperthyroidism A patient had typical acute agranulocytosis after six weeks' treatment with doses of 15–30 mg daily[31] The white count was reduced to 150 per c mm, with no polymorphs The patient recovered after blood-transfusion, penicillin, and pyridoxine In another case,[32] a fatal aplastic anæmia supervened after five months' treatment with carbimazole, the hæmoglobin level was 7 6 g per 100 ml, white cells 1500 per c mm (7% polymorphs), and platelets only 2000 per c mm The patient died from a cerebral hæmorrhage In his article on p 303 Dr Tait describes a fatal agranulocytosis in a man who had had carbimazole, this is apparently the third recorded death to be associated with this drug

These serious toxic reactions are admittedly rare, but when they do appear they strike suddenly and quick action is imperative The cases to which we have referred illustrate how these reactions may develop either early, as in the treatment of patients who are sensitive to the drug, or after a long course It cannot be said too forcibly that the drug must be stopped at the very first sign of a reaction, one patient who died had continued taking the drug for three weeks after the first purpuric rash had appeared[32] In treatment, blood-transfusion and penicillin are always advisable, for the rest, the progress of patients with agranulocytosis suggests that sodium pentosenucleotide pyridoxine, or vitamin-B complex make little difference to the outcome A bone-marrow examination is always useful because it is a good guide to prognosis[33] If recovery is going to take place, polymorphs return to the blood within two or three days

Since these drugs, and others like them, can do such damage, they must always be used with caution, and it might reasonably be asked whether some of them should be given at all On the other hand, as incidence of toxic changes is small, large and lengthy trials would be needed to prove that a new drug was invariably safe, and naturally, manufacturers are anxious to bring forward their more promising new products without delay Many manufacturers take great pains to secure evidence of freedom from toxicity, others have less exacting standards But whatever may or may not have been done before a drug is offered for general use, the surest safeguard is to look on every newcomer as potentially dangerous, and to be sceptical of confident statements to the contrary—for the first five years at any rate If a new drug is used only when there is a clear indication for it, and when hospital trial has firmly established its superiority over its more familiar predecessors, then the occasional reaction is a risk that is justified—and one that is taken every day when sulphonamides, chloramphenicol, or phenobarbitone are prescribed And the risk will be reduced still further if, at the first sign of sore throat, purpura or unexplained pyrexia, the patient is sent at once to hospital with a statement of the drugs he has had, in what dose, and for how long

Annotations

AN INCOME-TAX ANOMALY

We can hardly expect that our laws shall always be applied equally, for their application depends on people, and people, as we know, are various On the other hand we are entitled to demand that our statutes shall not discriminate against any group A small but important instance of such discrimination is the inequitable income-tax law which is at present applied to doctors engaged whole-time in the National Health Service

The law is clear Doctors who derive a substantial part of their income from private patients may, under Schedule D, offset against their income the cost of professional journals and books, and of attending scientific meetings The whole timers (under Schedule E) cannot do so—unless perhaps their contracts demand that they shall incur these expenses The discrimination does not end there For instance, the part timer can claim for relief from income tax the cost of professional motor car expenses not covered by the official allowance the full-timer cannot The part-timer can likewise claim for some of the cost of entertaining overseas doctors who are visiting hospitals or attending conferences in this country the whole-timer cannot

Besides whole-time consultants, other doctors and other professional groups are victims of this anomaly, which is not new but is felt more acutely than ever before because high rates of tax begin at lower real incomes Rationally the discrepancy is indefensible This was recognised by the Royal Commission on Taxation of Profits and Income in its declaration that "there is no good reason for treating Schedule E expenses less generously than Schedule D expenses, except to the limited extent that some difference of treatment is inherent in the nature of the two kinds of income" The Royal Commission concluded that the Schedule-E rule governing deductible expenses should be amended to permit the allowance of expenditure "reasonably incurred for the appropriate performance" of the duties of the office or employment

Owing to the rapid progress in diagnostic methods and in therapy, it is quite impossible for doctors to keep up a high standard without having books and journals *at their disposal and without attending meetings of* scientific societies These expenses are an unfairly heavy toll on those who, unlike their colleagues, cannot set them against income We earnestly hope that the Chancellor of the Exchequer will find it possible in the coming Budget to end this inequity

DIABETICS AND DRIVING

The judgment described on p 319 arose out of charges brought against a diabetic driver under the Road Traffic Act The Lord Chief Justice said "this section (of the Act [1]) was designed for the protection of the public, and if people were in a condition of health which rendered them subject to comas, or the remedies for which might send them into comas, they ought not to drive because of the danger which resulted to the rest of Her Majesty's subjects"[2] *Quite so the relevant section* of the Act says that "any person who when driving or attempting to drive or when in charge of a motor vehicle on a road or other public place is under the influence of drink or a drug to such an extent as to be incapable of having proper control of the vehicle shall be liable ", and there can be no serious contention that Lord Goddard's decision is anything but right in law The widespread interest that his ruling has aroused serves not only to waken public concern over diabetic drivers but also to illuminate a rather unsatisfactory section of an Act which daily increases in importance

How dangerous *is* the diabetic in charge of a motor vehicle ? It is clear from the small number of cases that come before the courts that few diabetics are, in fact a serious menace to their fellows On the other hand, a potential hazard does exist, and it remains to assess its dimensions In the first place, only those diabetics who require and receive insulin by injection are concerned Despite learned counsel's contentions, diabetic coma is always of slow onset, and most drivers would have time to relinquish charge of a vehicle in the several hours that pass before consciousness is lost And insulin requiring diabetics make up no more than 20–25% of the total diabetic population Diabetics who do not need insulin may be given it in error, but they are notoriously resistant to its action, and rarely suffer from hypoglycæmia Next, the great majority of insulin-requiring diabetics are well controlled, and, provided that they take their meals regularly and they do not engage in unusual physical exertion, they are not subject to attacks of coma It must be remembered that it is no crime to be in charge of a motor vehicle while under the influence of a drug it becomes a crime only when the drug's action prevents the driver from having proper control of the vehicle

There are five different types of insulin available, one in three forms, and all in three strengths Although dispensing errors are very uncommon, wrongly measured doses are by no means rare, and they account for most reactions in otherwise well-stabilised patients Rarely, reactions occur for no detectable reason, and they are usually attributed to sporadic endogenous production of insulin There remains a very small group of patients, chiefly young people, in whom control is difficult and who often suffer from hypoglycæmia and its consequences It is to these patients that Lord Goddard's remarks seem justly to apply

Diabetics are not alone in their liability to abrupt loss of consciousness Epileptics, for example, are similarly afflicted And since heart-attacks may recur, and often do, at moments of stress, should a patient who has had a coronary thrombosis likewise be excluded from driving ? What is the position of a patient who has *spontaneous* hypoglycæmic attacks ? Manifestly, the law needs some interpretation on this point, and de jure recognition of this is given earlier in the Act,[3] where provision is made *for the licensing of* handicapped drivers in certain circumstances—circumstances which would include all but a handful of diabetics Moreover, it receives much wider de-facto recognition from *most* licensing authorities by the issue of licences to known epileptics, provided that they are reputably certified as having been free from attacks for at least three years and are otherwise suitable persons to hold such licences

Clearly there can be no generalisations about diabetics, even insulin requiring diabetics, each case must be considered on its own, and *although* there are certainly some diabetics who would be a danger to Her Majesty's subjects when in charge of a motor vehicle, their number is undoubtedly small As the British Diabetic Association points out, one of the essentials for safety is that the driver should be able to recognise early the symptoms of hypoglycæmia, and those few who cannot do so should take medical advice before applying for a driving licence In fact, the small number to whom Lord Goddard's warning applies are usually the first to wish to be protected, and to protect the public, by not driving There remains, *however, the isolated* instance of the usually well controlled diabetic who has a hypoglycæmic attack at the wheel Provided it can be shown that the attack was unusual, unexpected, and in no known way attributable to the patient's negligence, he should not be held responsible for its consequences, and the Act should be amended accordingly

[3] Road Traffic Act (1930) section 5 (2b)

ARTERIAL PUNCTURE

Arterial puncture is being increasingly used in the course of diagnosis and treatment, and it is usually free from complications Even when the needle is of small calibre and of sound design, there is bound to be some trauma to the vessel along the track, and Crawford[1] has lately examined the way in which such wounds in arteries heal His material, mainly carotid arteries, was obtained at necropsy from patients who had been investigated by carotid angiography 4 hours to 240 days beforehand His findings suggest that the track, temporarily blocked with fibrin, is infiltrated with endothelial cells from the lumen of the artery in modified spindle cell and macrophage forms These cells form an avascular plug and derive their oxygen and nutrition by diffusion The surface is completely endothelialised in 6 to 8 days This avascularity of the endothelial plug is to be expected, since thin-walled capillaries would be unable to withstand the transmitted compressing force of the arterial blood-pressure near the intimal surface This type of organisation is comparable to that in a mural thrombosis on a vessel wall From the adventitial end of the track a more classical picture of repair proceeds, with fibroblasts and capillary loops As the scar matures further, collagen fibres thicken, and in four specimens with tracts 44 days or more old, smooth muscle cells were seen lying irregularly among the collagen fibres in the medial end of the scar the muscle coat was not, however, truly reconstructed.

This orderly repair of the damaged artery is very efficient, and few late complications of arterial puncture have been reported When trouble arises, it is usually because a large-bore needle has been introduced into a diseased artery in order to inject a radio-opaque solution rapidly and under high pressure Atheromatous plaques or mural thrombi may be loosened or, more disastrously, if the needle point is accidentally inserted into a branch of the aorta, the whole volume of irritant material may cause sudden thrombosis of the renal, cœliac, or mesenteric arteries and consequent organ infarction If the needle lies in the media of the aorta, the even more dramatic complication of dissecting aortic aneurysm may ensue Gaylis and Laws[2] believe that this is not uncommon and that it may account for many of the complications of aortography previously attributed to the irritating or toxic action of the contrast media Their patients recovered without serious sequelæ, though instances of paraplegia and death have been recorded The greatest care may not always avoid such complications, for Lindgren[3] showed that even when a trial injection confirms that the needle is in the lumen some of the medium may enter the wall during the main injection Aortic pulsation or respiratory movement may produce a small but vital shift in the position of the needle, and during forcible injection the needle may be pulled backwards or the chemical qualities of the injected medium may cause the artery to contract Intramural injections may well account for some of the femoral, carotid, or brachial thromboses which follow peripheral arteriography Moreover, it is known that in the occasional patient the brachial artery responds to trauma by a segmental spasm There can be little doubt too that the toxicity of sodium iodide or high concentrations of the organic iodides may cause endothelial or even parenchymatous damage Though arteries have a great capacity to withstand needling, high-pressure injection of irritant or bland solutions can be dangerous, and, on all counts, the reasons for advising a patient to undergo arteriography should invariably be scrutinised with care

"THE HURT MIND"

The fear of mental illness derives as much from misunderstanding and magical preconceptions as from simple ignorance The series of B B C television programmes, which ended on Jan 29, was designed both to counter old beliefs and to reveal new truths It is perhaps the most comprehensive attack yet made on the public's attitude to a medical problem, and it is to be welcomed as a sensible attempt to dissipate prejudice by information In introducing the series Mr Christopher Mayhew, M P, gave some idea of the size of the problem by pointing out that 1 person in 20 of the population of this country spends some time of his or her life as a patient in a mental hospital

The first programme introduced the theme that it is unjustifiable to look on mental disease as something very different from physical disease To collect material for the series Mr Mayhew was voluntarily admitted to a mental hospital for a few nights, and his excellent interviews with his fellow patients, the nurses, and the doctors helped to dispel the idea that mental patients are uncontrollable A modernised mental hospital, with its quiet, orderly wards and free access to the neighbourhood was contrasted with the old-fashioned institution—of which, unfortunately, there are still examples—with its high walls, locked doors, and patients pacing the airing-courts like captives Many people believe that mental patients must go into a mental hospital for treatment, but the programme showed that general hospitals now give outpatient treatment for mental as well as physical disabilities

The second programme was the least effective of the series It successfully gave an idea of the complexity of the brain by representing the number of its cells by the grains of salt in a specified number of cartons, but the definitions, couched in psychiatric phraseology, were unlikely to be helpful to many viewers The third programme described social and psychotherapeutic methods of treatment It showed that the first step in the reablement of the patient is to restore his sense of belonging to the community The fourth programme showed physical methods such as modified electroconvulsion, insulin shock therapy, and an ether abreaction a neurosurgeon described the operation of prefrontal leucotomy and its effects Patients then recounted their symptoms before treatment and after recovery The wife of a leucotomised patient gave a relative's point of view This was probably the most successful programme of the series and brought out clearly the similarity with physical disease and the improving prospects of recovery

Viewers were asked to send in questions and some 2000 did so In the last programme a panel of experts answered a selection dealing with overcrowding in mental hospitals, unsympathetic general practitioners the possibility of wrongful detention, and reablement, and Sir Geoffrey Vickers added a few words on the future of mental research Summing up, Mr Mayhew suggested that, though the social problem is vast and not yet generally recognised, the future looks hopeful

From the technical standpoint, the quality of production improved throughout the series In the earlier parts there was a tendency to suggest mystery by a haunting opening sequence and close ups of tapping feet and twisting fingers, but later the presentation was straightforward and more in keeping with the aim of the series In refraining from showing the faces of patients the producers—inevitably perhaps—were compromising with the very attitude they were attacking, for when the cameras recently visited a general hospital no such restriction was thought necessary

An associated series of six weekly mental health broadcasts will begin in the B B C Home Service on April 17

PREDNISONE AND PREDNISOLONE

ON Feb 1 prednisone and prednisolone were "released" for prescription on form E C 10, and practitioners were reminded of this by a flurry of literature from manufacturers of these steroids A confusing new family of proprietary names should not be allowed to submerge the official titles Prednisone and prednisolone are derived respectively from cortisone and hydrocortisone by the introduction of a double bond between carbon atoms 1 and 2 Pharmacologically, no important difference has been demonstrated between the two derivatives Hitherto they have been restricted to hospitals, but it seems unlikely that there will now be any very striking increase in their use General practitioners in this country were cautious towards cortisone when it became generally available and they will probably feel the same about prednisone and prednisolone They should certainly resist the reported efforts of one manufacturer to persuade them to give a combination of prednisolone and aspirin "for the mild to moderate rheumatic conditions encountered in general practice"

The scope and limitations of these two steroids can perhaps be best assessed by answering certain questions Are there any conditions in which they are the best form of treatment ? In what circumstances are they preferable to cortisone or hydrocortisone ? What are the indications for their use in rheumatoid arthritis and other chronic but generally non-fatal diseases ? What are their undesirable effects and what precautions should be taken to avoid them ?

When a steroid is the only drug which can benefit, even temporarily, a patient with a dangerous illness, or when such treatment is likely to prevent or reduce damage to important structures (especially in self-limiting conditions), the risk of serious side-effects must be accepted Such diseases are likely to be treated initially in hospital, and they include systemic lupus erythematosus, leukæmia, pemphigus, hæmolytic disease, thrombocytopenic purpura, certain ophthalmic conditions, and nephrosis Large doses are often needed in some of these diseases, and prednisone or prednisolone are preferable to cortisone because they are so much less likely to induce retention of sodium and water—a point which makes them particularly appropriate in nephrosis or in incipient heart-failure On the other hand, cortisone retains an advantage in the management of adrenal insufficiency In rheumatic fever cortisone is often used in preference to salicylate when the disease is particularly severe or when carditis is a prominent feature—though there is no proof that damage to the heart is reduced or prevented thereby For those who favour this policy, prednisone and prednisolone are attractive alternatives to cortisone

Except for disturbances of electrolyte metabolism, undesirable side-effects are about as common with prednisone or prednisolone as with cortisone in therapeutically comparable doses Peptic ulceration (which may be caused by a direct local action on the mucosa [1]) has been suspected to occur more often when the newer derivatives are used If the anti-inflammatory potency of prednisone or prednisolone is taken to be four times that of cortisone, treatment with the prednisone or prednisolone is about 40% more expensive

Rather more than a year ago we suggested [2] that experience with cortisone in the treatment of rheumatoid arthritis would make clinicians wary in the use of prednisone or prednisolone in that disease Little more can be added until the results of the controlled clinical trials now in progress have been made known The short-term benefit, albeit often dramatic, is unimportant unless it can, in large measure and with safety, be maintained indefinitely In a comparison of patients treated for six months [3] prednisolone proved slightly superior to hydrocortisone in some respects—but the differences were not statistically significant Certainly few clinicians would choose to use cortisone or its derivatives in early rheumatoid arthritis—when the chances of a natural remission within the next few months are good—or in patients over 60, in whom the dangers of osteoporosis and vertebral collapse are very real If prednisone or prednisolone is given in rheumatoid arthritis, it is sound practice to use the smallest effective dose (which can sometimes be timed so as to reduce the morning exacerbation) and to supplement this with aspirin The combination of prednisolone and aspirin in one tablet cannot, however, be justified, for it deprives the clinician of his freedom to regulate the dose of each component separately Treatment of asthma poses rather similar problems, but the limitations of continuous treatment can be set against the efficacy of short courses for acute seasonal episodes in patients who are resistant to other treatment and in patients with severe status asthmaticus [4]

The contra indications to cortisone and the precautions to be taken during its use apply equally to prednisone and prednisolone—except that the newer steroids may be used with less fear of fluid retention Treatment may reactivate a quiescent tuberculous focus, and a preliminary chest radiograph is a wise precaution An existing peptic ulcer is likely to become worse and may bleed or perforate, and unless the drug has to be used to save life, a history of peptic ulcer is a contra indication A case can be made for giving aluminium hydroxide to prevent peptic ulcer the efficacy of this precaution has not been tested, though Bollet et al [5] recorded two cases in which peptic ulcers which had developed during the administration of prednisone showed signs of healing after treatment with diet and aluminium hydroxide, despite the fact that the patients were still on prednisone Caution is also needed in patients with a history of mental disorder or with signs of mental instability Relative contra indications include diabetes mellitus and hypertension, though an increase in blood pressure is not common during treatment with prednisone or prednisolone Patients suffering from renal disease with nitrogen retention do not do well The precautions that should be taken during treatment include periodical checks of blood pressure, tests for glycosuria, and inquiry for symptoms of dyspepsia There is no simple method for detecting the development of a dangerous degree of osteoporosis, and the difficult task of appraising prophylaxis with testosterone and œstrogens remains to be accomplished

Like cortisone, prednisone and prednisolone suppress endogenous adrenocortical activity, and this effect, which may continue for some months after a long course of treatment, may be dangerous if the patient has a major illness or requires a surgical operation The adrenocortical insufficiency then calls urgently for an increased dose or temporary resumption of steroid therapy, and it is important that a hospital admitting such a patient should know that he is taking, or has recently taken, cortisone or one of its derivatives Surgeons need not fear that normal doses of these drugs will interfere with the healing of wounds

From the Pædiatric Unit, St Mary's Hospital Medical School, and St Mary's Hospital, London

THE transformation of medicine from an art into a complicated science and technology has altered the functions and increased the status of hospitals Founded originally as the medieval refuge for oppressed or destitute persons, they have now become centres for the diagnosis and treatment of disease in all classes of the population The gain from concentrating medical resources is clear, there are, nevertheless, penalties in the overuse of hospitals, especially for children "Few will dispute," says a recent World Health Organisation report, "that the best place to care for a child is in his own home among familiar surroundings, where the people who normally give him security and affection can tend to his needs" (Capes 1955)

Quite apart from humanitarian considerations, there are concrete dangers in admitting young children to hospital on the one hand, cross-infection (Allison et al 1946, Watkins and Lewis Faning 1949), on the other, isolation, which distorts emotional development, can hinder recovery (Bakwin 1942), and is often followed by symptoms of emotional disturbance (Bowlby 1951)

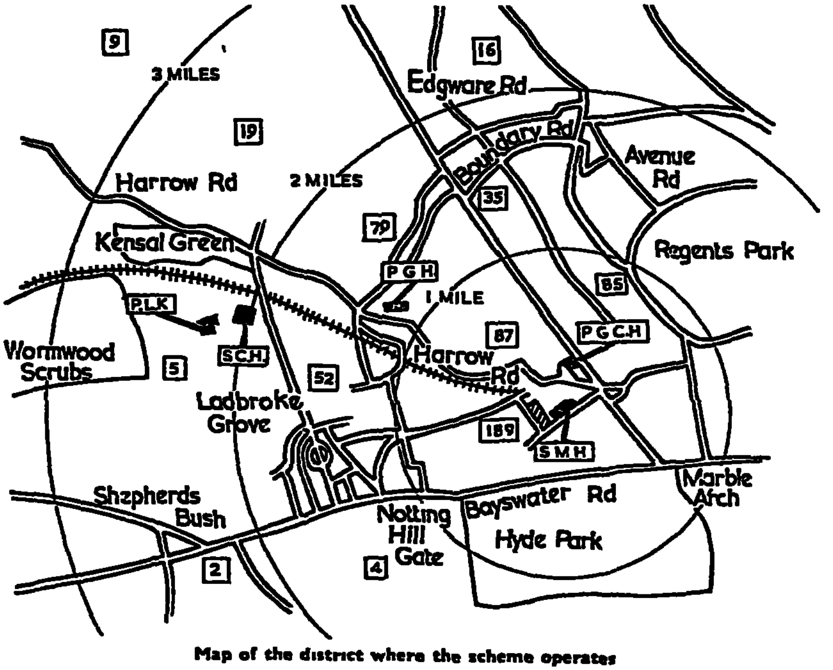
Another disadvantage is the resulting break in the continuity of medical care Responsibility for the patient passes into the hands of the hospital staff, and decisions that could affect the child's whole future may be taken without reference to the family doctor, normally the person best able to relate an illness to its social context Such a reduction in the influence and responsibility of the family doctor is not in the patient's interests, especially in pediatrics where symptoms are often pointers to a strain involving the whole family Moreover, lack of common experience between the general practitioner and the staff of a teaching hospital often means that students are being taught more about "specialist" medicine and less about the everyday problems of family practice—a weakness of modern teaching hospitals not peculiar to pediatrics

Yet another disadvantage of inpatient treatment is its high and mounting cost This in itself demands that a recommendation for admission should be fully justified on the grounds of medical need

Organised Home Care

Domiciliary medicine is the province of the family doctor, but in recent years a number of hospital home care projects have been started which provide special medical and nursing services on a domiciliary basis Hospital home care probably grew out of the old dispensaries founded as charities in 18th-century England It has developed somewhat differently on the two sides of the Atlantic—in America (Bluestone 1954) providing a substitute for private practice, and in Britain supplementing general practice In England, trials have been made of two different patterns of home care for sick children (Lightwood 1956)

The first pattern consists in a home nursing service in which visiting nurses carry out the instructions of the general practitioners Thus, if the doctor requires professional assistance he obtains it by means of a domiciliary consultation, and should his patient need to go into hospital he surrenders his charge for the time being Already in England there are two such schemes for children One is a home nursing unit set up in Rotherham in 1948 (Gillet 1954), and the other a somewhat similar scheme started in Birmingham in October, 1954 (Smellie 1956), in Rotherham there is no direct connection with the hospital services, but in Birmingham newly appointed visiting nurses are welcomed at the children's hospital for a brief refresher period In these two schemes the public-health committee provides a service of visiting nurses, as any comparable health authority has the power to do—the degree to which it is done depending on local keenness in the matter Provided suitable staff can be obtained, a home nursing service is easily organised



Map of the district where the scheme operates

The figures in squares refer to the number of cases dealt with in the areas bounded circumferentially by the 1 2, and 3 mile limits and radially by the Harrow, Edgware, and Bayswater Roads, St Mary's Hospital being the centre of the circles

The local hospitals with children's beds are shown as follows

S M H	St Mary's Hospital
P G C H	Paddington Green Children's Hospital
P L K	Princess Louise (Kensington) Hospital for Children
P G H	Paddington General Hospital
S C H	St Charles Hospital

The first three belong to St Mary's Hospital group *and simple to work, many admissions to hospital* can be prevented, and valuable educational work is carried out by the nurses

The second pattern of pædiatric home care represents the extension of hospital work into the patient's home at the request of and in cooperation with the family doctor (Lightwood, Brimblecombe, and Davis 1956) A project of this type was started in April, 1954, at St Mary's Hospital, London, to redress what we believed to be a faulty balance between hospital and domiciliary practice, for we had found that nearly a quarter of the children in hospital during a review period were admitted *for conditions which could have been managed at home* if the doctors had possessed the facilities and experience required, and that there were other children whose stay in hospital could have been shortened These considerations led the board of governors of St Mary's Hospital, having first consulted the local health authorities, the local medical committee for the County of London, and the Paddington and St Marylebone District Nursing Association, to authorise, and finance from endowment funds, a trial of home care with the following programme

(1) To discover how far, and in what conditions, sick children who would otherwise be in hospital can be nursed at home under the care of general practitioners supported by a mobile hospital team

(2) To determine whether the liaison between the pædiatric staff of the hospital and the general practitioners is thereby improved

(3) To compare the cost of inpatient treatment with the cost to the hospital of such home care arrangements

CHOICE OF DISTRICT

The district chosen for the trial included most of the borough of Paddington and a part of the borough of Marylebone—an area with a population of more than 75,000 (see map) The boundary was drawn after consultation with the local medical committee of the County of London and the London County Council in such a way that journeys would seldom exceed two miles, but as flexibility is essential in a home care scheme the team has not hesitated to go outside the boundary when circumstances have warranted The district has a high proportion of poor and overcrowded houses and a shifting and partly immigrant population, also many Paddington families have been in the habit of taking their children when sick direct to the hospital, rather than calling in a general practitioner For these reasons the locality chosen was by no means favourable for the trial of a home-care project

ORGANISATION

A mobile team, fully trained in pædiatric work, has been established to answer calls from family doctors It consists of two pædiatricians, a sister, two nurses, and a part time physiotherapist One of the pædiatricians, giving part time service, devotes himself primarily to consultations, the other, an experienced senior registrar, is responsible for records and liaison, the carrying out of technical procedures, and the day to day supervision of treatment The sister and nurses, who have both general and sick children's nursing certificates, carry out treatment, assist with technical procedures, instruct the mothers in bedside nursing and infant feeding, and keep the usual nursing records They are available for night duty, which is reassuring for the parents, though they are seldom required

A car for morning and evening rounds is provided by the London County Council Full ancillary services, including those of the almoner, the laboratory, diagnostic radiology, use of outpatient operating-theatre and other technical assistance, are available The cost of salaries, equipment, transport, office, and telephone is borne by the endowment funds of St Mary's Hospital

A summary of this expenditure is given in table I, some of the items being estimated The service was paid for entirely out of endowment funds and claims were not made on the National Health Service in respect of *domiciliary consultations*

TABLE I—EXPENDITURE FOR THE FIRST TWO YEARS OF THE HOME CARE SCHEME

—	1954–55	1955–56
	£ s d	£ s d
Salaries and wages

Others	162 5 6	[illegible]
Accommodation	100 0 0	160 [illegible] 3
Use of L C C car and other transport	948 9 8	1094 12 3
X ray and pathological services	335 0 0	635 0 0
Other expenditure	174 13 0	378 5 9
—	£5103 17 1	£6116 18 3

MODE OF OPERATION

When a general practitioner needs the help of the team, he telephones the hospital If possible a bedside consultation is arranged, but in some cases it is more convenient to discuss the situation over the telephone If the case proves suitable for home care, the agreed diagnostic and therapeutic measures are undertaken straight away, thereafter the nurses and registrar keep records and notes as in hospital Liaison is maintained by further meetings, by telephone, or by letter, as circumstances dictate, changes in the régime being reported and discussed The patient remains the responsibility of the family doctor throughout No canon of working is applicable to all circumstances, so in each case the general practitioner and the team need to agree at the start on their respective roles

With the cooperation of the various departments, all the diagnostic and therapeutic resources of the hospital can be deployed in the patient's home as required On completion of treatment, the health visitor is told about young children who have been dealt with by the team.

The following example gives an illustration of the kind of work performed

A male infant, aged 12 weeks, had been fretful and feverish with otitis media for three days, and there had been no response to penicillin The family doctor then asked for the assistance of the home care team Bacterial meningitis was diagnosed and confirmed by immediate lumbar puncture Treatment was instituted and a nurse stayed with the child for the night Next day he was well enough to be left in the care of his mother, and within forty eight hours he was almost himself again There was no interruption of breast feeding and little disturbance of the home routine Swabs were taken from the other members of the family, and when the infection was found to be meningococcal each received prophylactic sulphonamide Supervision by the team continued for ten days and when, some months later, the infant was re examined, he showed no sequelæ of the illness

CASE MATERIAL

During the first two years of the project, the home care team cooperated in the management of 582 patients,

TABLE II—PATIENTS RECEIVING HOME CARE BY THE TEAM APRIL 5, 1954, to MARCH 30, 1956

Month	New patients		Cumulative total		No of patients under care per month		Bed nursing days per month	
	1st year	2nd year	1st year	2nd year	1st year	2nd year	1st year	2nd year
April	4	23	1	229	2	16	52	477

December	22	42	110	459	19	31	589	940
January	29	41	130	500	16	27	619	437
February	27	41	166	541	19	31	512	906
March	40	41	206	582	21	30	610	915

including cases of nearly all the medical diseases normally encountered in a children's ward Inevitably this has influenced the type of case admitted to our wards, in particular there has been an increase in the proportion of surgical and accident cases, and the medical cases admitted have tended to be more urgent and severe (except for medical patients living outside the home care district) Comparison of home-care cases with current ward admissions shows a bias towards the less urgent conditions, nevertheless serious medical cases are often accepted for home care, including some incurable conditions

Of 3 patients who died while under supervision by the team, 2 were children with severe congenital defects whose deaths were inevitable and expected, the third was an infant who was convalescing from a respiratory infection and approaching the end of a course of chemotherapy When seen at home a few hours before his sudden death, his condition gave no cause for anxiety and there seemed to be no indications for admission to hospital A *post mortem* examination was made and this showed only an early bronchopneumonia

Table II shows the accumulation of the 582 patients who were referred for home care during the first two years

Of these, 460 were nursed at home throughout their illness, 31 were admitted to hospital for part of their treatment, 16, after a domiciliary consultation, were considered not to need the services of the team, and 75 were transferred from hospital to complete their treatment

Origin of Cases—Table III shows the origin of the cases The majority were undertaken after an initial request from general practitioners, a smaller number came on the recommendation of outpatient or casualty department staff, or as early discharges from hospital, the family doctor being asked for his approval

TABLE III—ORIGIN OF CASES

—	April to Sept 1954	October 1954 to March 1955	April to Sept 1955	October 1955 to March 1956
From family doctors	16	98	66	154
From outpatient and casualty departments	22	41	50	60
Transferred from wards	22	7	27	19

It will be seen that the number and proportion of patients directly referred by family doctors increased as the scheme got into its stride Of one hundred and fourteen family doctors whose patients have been dealt with under the scheme, thirty-seven first used it on their own initiative and seventy seven as a result of a case being referred from hospital, of the latter twenty-three subsequently called in the team to help with another case Among the sixty doctors who chose to use the scheme five used it in more than 20 cases, thirteen in from 10 to 20 cases, ten in from 5 to 10 cases and thirty-two in from 1 to 5 cases

Age distribution—33% of the patients were infants and 30% were toddlers (1–4 years old)—the two groups that most pædiatricians feel are best kept out of hospital if possible

Housing

Full records were kept of the home conditions under which the patients were nursed This information is not easy to classify, on the whole, the quality of a home is more a reflection of the parents' way of life than of their housing 20 cases were rejected because the home was poor or overcrowded in 6 cases nursed at home the parents said they thought that their housing had been inadequate for home care, and in a further 15, experience was such that the team would not agree to look after a sick child in that home again

PROCEDURES

Experience has shown that the following procedures can be carried out efficiently and safely, even in poor homes

Diagnostic

- Test feeding
- Catheterisation
- Venepuncture
- Lumbar puncture
- Pleural aspiration
- Duodenal intubation
- Estimation of basal metabolic rate and respiratory quotient
- Fat balance
- Subdural tapping

Therapeutic

- Surgical dressings
- Removal of stitches
- Removal of plasters
- Ephedrine replacements
- Setting up steam tent
- Administration of oxygen (by mask)
- Administration of intravenous fluids, including blood
- Continuous limb traction
- Physiotherapy

RELATIONS WITH FAMILY DOCTORS AND PARENTS

In practice, contact with the family doctor, while always sufficient to ensure proper treatment of the patients, was sometimes not close enough to realise fully the main object of the scheme—a closer rapport between hospital and family doctors Experience soon showed that it was difficult for a busy family doctor to keep in close enough touch with the nurses in a serious case, and that the best arrangement was for the registrar to undertake supervision of such patients on his behalf In less urgent cases, some family doctors delegated their authority to the medical members of the team, retaining only a watching brief, while others preferred to manage the case independently after an initial consultation With a third group, mostly doctors with a high proportion of children amongst their patients, relations were close and satisfactory, and these doctors soon came to use the scheme regularly In no case was home care abandoned because of difficulties between the team and the practitioner concerned, and only once did a doctor decide against using the scheme when invited by the hospital to do so

Nearly all the mothers proved to be reliable, observant, and efficient in nursing Few complained of the extra work involved on the contrary several stated that home care made things easier by saving them anxiety and the burden of visiting hospital The few who criticised the scheme did so on the grounds that their housing was unsuitable, these were not cases referred by a general practitioner

The presence of the parents often makes it harder to examine a child and to carry out special procedures, but it has the advantage of making the examiner temper his thoroughness with a sense of proportion It is essential for the doctor to be thoroughly trained, for an unsuccessful lumbar puncture or venepuncture at home would be a minor disaster leading to loss of confidence all round

RÔLE OF THE NURSES

Pædiatric nurses working in hospital have to play a mother's part in which they can develop a close and rewarding relationship with their patients Home care nursing is less personal and the nurses must be prepared for mother and child to be united in dislike of their ministrations when these prove painful or disturbing Inevitably their relationship with the mothers needs to be closer than that with the child, and a talent for dealing with children is less valuable than a capacity for appreciating the point of view of their parents Our nurses avoided a missionary rôle, but their example and frequent presence in the house led some mothers to raise their standards of houskeeping With help and advice from district nurses, the art of making the best use of sometimes meagre household resources was learnt, and the uncertain tempo of the work was not unexpected What and simple to work, many admissions to hospital can be prevented, and valuable educational work is carried out by the nurses

The second pattern of pædiatric home care represents the extension of hospital work into the patient's home at the request of and in cooperation with the family doctor (Lightwood, Brimblecombe, and Davis 1956) A project of this type was started in April, 1954, at St Mary's Hospital, London, to redress what we believed to be a faulty balance between hospital and domiciliary practice, for we had found that nearly a quarter of the children in hospital during a review period were admitted for conditions which could have been managed at home if the doctors had possessed the facilities and experience required, and that there were other children whose stay in hospital could have been shortened These considerations led the board of governors of St Mary's Hospital, having first consulted the local health authorities, the local medical committee for the County of London, and the Paddington and St Marylebone District Nursing Association, to authorise, and finance from endowment funds, a trial of home care with the following programme

(1) To discover how far, and in what conditions, sick children who would otherwise be in hospital can be nursed at home under the care of general practitioners supported by a mobile hospital team

(2) To determine whether the liaison between the pædiatric staff of the hospital and the general practitioners is thereby improved

(3) To compare the cost of inpatient treatment with the cost to the hospital of such home care arrangements

CHOICE OF DISTRICT

The district chosen for the trial included most of the borough of Paddington and a part of the borough of Marylebone—an area with a population of more than 75,000 (see map) The boundary was drawn after consultation with the local medical committee of the County of London and the London County Council in such a way that journeys would seldom exceed two miles, but as flexibility is essential in a home-care scheme the team has not hesitated to go outside the boundary when circumstances have warranted The district has a high proportion of poor and overcrowded houses and a shifting and partly immigrant population, also many Paddington families have been in the habit of taking their children when sick direct to the hospital, rather than calling in a general practitioner For these reasons the locality chosen was by no means favourable for the trial of a home-care project

ORGANISATION

A mobile team, fully trained in pædiatric work, has been established to answer calls from family doctors It consists of two pædiatricians, a sister, two nurses, and a part-time physiotherapist One of the pædiatricians, giving part time service, devotes himself primarily to consultations, the other, an experienced senior registrar, is responsible for records and liaison, the carrying out of technical procedures, and the day-to day supervision of treatment The sister and nurses, who have both general and sick children's nursing certificates, carry out treatment, assist with technical procedures, instruct the mothers in bedside nursing and infant feeding, and keep the usual nursing records They are available for night duty, which is reassuring for the parents, though they are seldom required

A car for morning and evening rounds is provided by the London County Council Full ancillary services, including those of the almoner, the laboratory, diagnostic radiology, use of outpatient operating-theatre and other technical assistance, are available The cost of salaries, *equipment, transport,* office, and telephone is borne by the endowment funds of St Mary's Hospital

A summary of this expenditure is given in table I, some of the items being estimated The service was paid for entirely out of endowment funds and claims were not made on the National Health Service in respect of domiciliary consultations

RELATIONS WITH FAMILY DOCTORS AND PARENTS

In practice, contact with the family doctor, while always sufficient to ensure proper treatment of the patients, was sometimes not close enough to realise fully the main object of the scheme—a closer rapport between hospital and family doctors Experience soon showed that it was difficult for a busy family doctor to keep in close enough touch with the nurses in a serious case, and that the best arrangement was for the registrar to undertake supervision of such patients on his behalf In less urgent cases, some family doctors delegated their authority to the medical members of the team, retaining only a watching brief, while others preferred to manage the case independently after an initial consultation With a third group, mostly doctors with a high proportion of children amongst their patients, relations were close and satisfactory, and these doctors soon came to use the scheme regularly In no case was home care abandoned because of difficulties between the team and the practitioner concerned, and only once did a doctor decide against using the scheme when invited by the hospital to do so

Nearly all the mothers proved to be reliable, observant, and efficient in nursing Few complained of the extra work involved on the contrary several stated that home care made things easier by saving them anxiety and the burden of visiting hospital The few who criticised the scheme did so on the grounds that their housing was unsuitable, these were not cases referred by a general practitioner

The presence of the parents often makes it harder to examine a child and to carry out special procedures, but it has the advantage of making the examiner temper his thoroughness with a sense of proportion It is essential for the doctor to be thoroughly trained, for an unsuccessful lumbar puncture or venepuncture at home would be a minor disaster leading to loss of confidence all round

RÔLE OF THE NURSES

Pædiatric nurses working in hospital have to play a mother's part in which they can develop a close and rewarding relationship with their patients Home care nursing is less personal and the nurses must be prepared for mother and child to be united in dislike of their ministrations when these prove painful or disturbing Inevitably their relationship with the mothers needs to be closer than that with the child, and a talent for dealing with children is less valuable than a capacity for appreciating the point of view of their parents Our nurses avoided a missionary rôle, but their example and frequent presence in the house led some mothers to raise their standards of housekeeping With help and advice from district nurses, the art of making the best use of sometimes meagre household resources was learnt, and the uncertain tempo of the work was not unexpected What proved more difficult were human factors—the maintenance of morale, the acceptance of rather limited authority, and the realisation that the blind trust placed in hospitals is not necessarily extended to those doing similar work in private houses

The nursing team make about twenty-five visits a day, fifteen in the morning "round" and ten in the evening In cases of anxiety, one of the nurses stays on till the danger is over in less serious cases one to three visits daily are necessary in convalescence three visits a week commonly suffice Usually the nurses spend about ten minutes with each patient, but sometimes, when the household are agitated or some special procedure has to be done, they will have to remain for an hour or more Most families are satisfied with an approximate indication of the time of the next visit and this makes for a flexible time table, especially when the telephone is available The time spent in travelling from case to case averages about five minutes, and each visiting round lasts about four hours

Discussion

The practicability of home care for any given patient depends on whether the treatment involves the use of fixed hospital equipment, on the nature of the living accommodation, and on the willingness of those concerned (the family, the family doctor, and the leader of the hospital team) to accept the added responsibility entailed Thus it is not possible to say which diseases are suitable for home care except in a broad way Patients with nearly all the acute and chronic diseases commonly met with in the wards of children's hospitals have been treated without serious difficulty, including 3 who died, yet there are many cases in which hospital admission is the best solution, as when the mother is overburdened, unable to accept the added responsibility, or not sufficiently intelligent to fill a nurse's rôle, or when there is a risk of a dangerous situation arising in the absence of those able to deal with it

Home care has a special place in the following cases

(1) In the treatment of infants with medical conditions (*such as feeding difficulties and gastro enteritis*) where also there are many opportunities of giving education in preventive measures

(2) In children under 5 years of age, for a severe illness *may lose much of its misery when they can stay at home*

(3) In older children with chronic or incurable illness, since a long stay in hospital would deprive them of joining in family life at home Moreover, in a long term illness a great saving of hospital beds is possible

Some of the practitioners have said that the diagnostic facilities of our home care service are particularly helpful A consultation on a sick child is much more useful to a hard-pressed *doctor* when *all necessary investigations* can be carried out on the spot and the results reported back promptly for discussion Without these facilities it had previously often been necessary to arrange admission for investigations now shown to be feasible at home

Although the structure of the National Health Service provides a background *favourable for organised* home care, success of a home-care project will turn on whether it is wanted by the public and the *family doctors* Therefore it will be asked whether the project at St Mary's Hospital offers more to our patients and their doctors than services already available—i e, domiciliary consultations, visits by *district* nurses and health visitors, and X-ray and laboratory diagnostic facilities The doctors who have used the project find that, through it, these services can be deployed more promptly and efficiently for the benefit of sick children whom in the past they would have been forced to send into hospital, and they are given an opportunity of sharing responsibility without surrendering it, and of keeping in touch with the hospital staff and scientific progress

TABLE IV

—	Cost per patient per week	Cost per case
	£ s d	£ s d
Home care scheme	4 1 0	16 5 4
Princess Louise (Kensington) Hospital for Children	29 19 8	52 0 0
Paddington Green Children's Hospital	25 15 3	32 15 1

COMPARISON OF COST

It is impossible to make a direct comparison between the cost of home care and that of hospital care This is because the cases are differently selected, the criteria for admission and discharge are dissimilar, and the home care project depends on the parent hospital A comparison depending on the relative cost per week is less reliable than one based on cost per case (table IV) because the duration of home care supervision is influenced by the fact that "discharge" is less urgent than with hospital care The comparative costs for the second year of the scheme given in table IV show that with home care organised on these lines the cost per home care patient (incurred by the hospital) was considerably less than the cost per patient in hospital

EDUCATIONAL VALUE OF HOME CARE

Home care has great educational value Some mothers, especially younger ones, seem to gain in character by nursing their children through an illness, others come to realise that the treatment of illness, even by the most modern methods, is all in the day's work and not a mysterious rite *practised* only by initiates in hospital surroundings This realisation may help them to trust their own common sense in minor illness and to rely on their family doctor rather than taking the child directly to hospital In addition, home care helps many parents to realise why their child has become ill and how to prevent a recurrence, whereas if he had gone into hospital he might have returned to the same unsatisfactory conditions which caused his illness

Of those engaged professionally, it would be difficult to say which party has profited most from experience shared by all The nurses, previously trained in hospital, were doing home nursing for the first time and gaining an insight into human character and maternal problems which could hardly have been learnt in hospital The medical members of the team have certainly gained immeasurably by their contacts with the practitioners and by their experience in domiciliary pædiatrics Such experience can be a real asset in teaching students, either directly as when the students accompany members of the team on domiciliary visits, or indirectly through the influence which the work can have on the teacher's clinical outlook, also enabling him to appreciate better what general practitioners need when they refer a patient for consultation, and providing him with a more real understanding of social medicine

Summary

There are disadvantages in removing sick children to hospital for treatment A high proportion of pædiatric cases can be nursed safely and efficiently at home when the family doctor is given the support of a *mobile* hospital team

Home care is less expensive than hospital care, and has an educational value Both hospital personnel and general practitioners can benefit from cooperating directly in the care of a patient

Home care requires the exercise of tact, sympathy, and a high standard of medical etiquette in *order to prevent* misunderstandings and overcome difficulties

Throughout the planning and operation of the scheme, we have had the coöperation of the local medical committee of the County of London, the Paddington and St Marylebone district nursing association, the London County Council, the local medical officers of health, and the constituent hospitals of the St Mary's Hospital group Our grateful thanks are due to the members of these bodies

MOTHER AND CHILD

ON Jan 30 Dr MARGARET MEAD delivered the 8th Ernest Jones lecture of the British Psycho-Analytical Society Dr Mead's contributions to psycho analytical understanding through her study of social anthropology, and her use of psycho analytical concepts in her field-work, are well known In this lecture on changing patterns of parent relations in an urban world, she was enlarging on the way in which observation of mother-child relationships in more primitive societies could throw light on what those who live in an urban society wanted to achieve in this sphere and on the difficulties they encountered

A film of the care of a newly delivered baby in New Guinea showed the very close physical contact between mother and baby, from a few minutes after birth In New Guinea there was not even clothing to intervene between mother and baby The baby was introduced to the world by a breast feed from a lactating neighbour, a few minutes after he had been born Within a day he was suckled by his mother, who cared for him with calm assurance Dr Mead showed how this type of mother-infant relationship threw into relief some of the present-day problems of mothers and babies Perhaps most interesting was Dr Mead's thesis that in a primitive society weak babies did not survive and were not expected to A puny infant who did not suck well provoked anxiety in his mother by failing to thrive, and her anxiety diminished her capacity to produce the milk essential for the baby's survival In this way babies who failed to achieve a satisfactory relationship with the mother, whether for physical or psychological reasons, actually died

In modern society all babies are expected to grow up and nearly all of them in fact do so But the responsibility for their survival is thrown on the mother, there is a tendency to speak of "good" and "bad" mothers rather than "good" and "bad" babies The cost in maternal guilt can hardly be measured and must play a profound part in the current uncertainty of aim in child-rearing Actually the morally tinged words "good" and "bad" should not be applied to either mothers or babies in this context It is how the particular mother and baby respond to each other, within their social setting which is of importance for the future emotional development of the child Both psycho analysts and anthropologists have separate, yet overlapping, parts to play in developing an understanding of these responses and their results

It was fitting that this tribute to Dr Ernest Jones, who contributed so much to the study of psycho analysis in Britain, should have been made by an anthropologist whose field work has so often confirmed what analysts have deduced from their study of individual patients

Medical Education

REFLECTIONS

D A K BLACK
M D, B Sc St And, F.R C P
READER IN MEDICINE, UNIVERSITY OF MANCHESTER

TEN years in the practice of medical teaching in a large and active school have left me little leisure in which to systematise whatever impressions I may have acquired However, a recent short visit to the United States has allowed me the luxury of calm reflection and has even stimulated me to make some comparisons which I hope may not prove too odious In this self-appointed and otiose task I draw both strength and responsibility from the monitory words of R L Stevenson, who wrote

> "Perhaps there is no subject on which a man should speak so gravely, as that industry, whatever it may be, which is the occupation or delight of his life, which is his tool to earn or serve with, and which, if it be unworthy, stamps itself as a mere incubus of dumb and greedy bowels on the shoulders of labouring humanity"

In my submission, the general aims of a medical school are to find good students, to impart to them a system of technique, a body of knowledge, and also an outlook on medicine which will leave them with both the desire and the capacity to accept the changes and accretions in knowledge which will surely come, to do all this in such a way that their time will not be wasted, their enthusiasm damped, and their maturity postponed by an enforced submission to evanescent authority, and finally to set them, not ungrateful, on the narrow way between brittle self-confidence and unhelpful hesitancy For aims such as these, good teaching is a necessary, but not a sufficient, condition, there must also be examples of clinical care, of scientific critique, and of the advancement of learning Just as many philosophers have thought that happiness comes as a by-product of the pursuit of other ends, so I would boldly say that an excessive preoccupation with pedagogy, and in particular with its mechanical aids, may be an actual hindrance, in that it diverts enthusiasm and time from clinical and investigative work, which supply the true content of medical teaching Interest and clarity should stem directly from content, and not be conscious additions to pedestrian material

Before discussing the various means which are available to us in the pursuit of these aims, I would direct attention to two distinctions which are commonly made in discussions on medical education, but which seem to me prolific sources of verbiage and confusion, in that each of them is based on an outlook which is false, or at best incomplete I refer to the distinction between science and art in medicine, and to that between an academic and a practical education

Taking the distinction between science and art, it seems to me that in the practice of medicine we use our minds in a number of ways, which include the deliberate use of experiment, whether laboratory or clinical, the simple observation of Nature, either at first or at second hand, and the making of practical decisions, often in circumstances where our action will be the beginning rather than the conclusion of an experiment, and where we may have little guidance from our own experience or that of others. (Each new therapeutic agent poses this kind of problem) Now, a narrow definition of science (as experimental testing of hypotheses) would include only the first of these, a wider definition of science, based on the fact-finding which should precede hypothesis, would include the second *mode of thought* as well, but the third type of mental activity, which embraces the practical application of the first two, would scarcely be included in any reasonable definition of science Moreover, the planning of scientific observations and experiments is itself an art These various activities of the mind may require isolation for purposes of discussion, but this is an artificial process, and an education based exclusively on one of these types of mental activity would be grossly incomplete

Again, the distinction between a "practical" and an "academic" education means very little, at least to me I may not be understanding the issues involved, but "know-how" is scarcely of value unless attended by "know-why" and "know-when" It is a witless task to ascribe priority as between theoretical knowledge and practical skill, for the one cannot get along without the other *At times, the right action may be inaction* (fortunately, it was an American who composed the guileful epigram—"Don't just *do* something, John *stand* there") If medical practice were made up of eternally valid stereotypes of procedure, it could be taught by rule of-thumb methods, but we all know that in medicine, as in life, the problems encountered are infinitely various, providing the truthful component of that veteran cliché "Each case must be judged on its merits" It seems plain that a medical training must inculcate both knowledge of currently accepted practical routines, and an ability to depart from or modify them in new situations

SELECTION OF STUDENTS

At the age when most students in this country apply for entry to medical school, they are in practice, if not in theory, selected largely on the basis of their showing in General Certificate of Education (advanced level) Reports from headmasters would often be of great value (positive or negative) if the headmaster himself were the applicant, but in assessing the students, with honourable exceptions, *they are less helpful* The *10–15* minutes' interview gives a few applicants an opportunity for self-elimination, and others give evidence of great promise, which may even be fulfilled, but the findings at interview rarely deviate from those predictable on examination results More elaborate selection procedures have been described, but there is no solid evidence that their results justify the added load on teaching staff The main defect of selection by G C E results is the admission of the occasional student who can reproduce the input of intensive coaching, but who cannot learn for himself in a university (I am not being cynical about this in the long run, we must be able to teach ourselves, and to criticise what others teach us, and if a university encourages us to do this, it is doing its job) The American medical schools seem to me to have an advantage here, in that their applicants have already had their chance to prove themselves under university-type conditions for three years, so that the selecting school has more to go on, and there may be less compunction in rejecting people who at least have a modest college degree than in excluding people who have done badly in anatomy and physiology If the "premedical subjects" are used as a screen, we run the risk of excluding otherwise adequate students who have had no satisfactory schooling in science, and are merely slow in coming to terms *with it*

CONTENT OF THE MEDICAL CURRICULUM

The present medical curriculum is a sort of Christmas tree, in which a conventional basic structure (common to *all* schools, *stereotyped* by regulation, and scarcely altered since 1900) has been decorated with tinsel and fairy lights (varying from school to school, and reflecting the localised enthusiasms of teaching staff) There has been much criticism, and this has very properly been based on the burden which such a curriculum lays on the medical student The outstanding student can take it, but his less *gifted* colleague, even if he scrapes through all the examinations, becomes dispirited by the mass of factual information I am *quite unashamedly* with the pruners rather than with the decorators, and three changes in the past year or two seem to me to enhance the case for vigorous pruning

The first two are the compulsory postgraduate year and the increasing recognition that "general practice" needs some measure of postgraduate training as much as any "specialty" These two things seem to me to legitimise something which has in any case come about from the pressure of events—that the student no longer leaves us fully armed against all medical contingencies (did he ever do this?), and that we on our part need not lie awake at nights if he should slip through our meshes *ignorant* of the insertions of certain muscles, the posology of each of the *British Pharmacopœia* preparations of mercury, or even of the factors governing sodium reabsorption in the renal tubule

Thirdly, in the past year, the curriculum committee of the General Medical Council has made recommendations which are permissive, and no longer restrictive If these are accepted by the council, the individual schools will have the responsibility and opportunity of planning a course which may allow students to think and do more, and sit and suffer less

The task of refining the content of the medical course will be long, and the result will itself require revision as the years speed past Sectional interests will impede the process, and the ultimate beneficiaries, the students, will probably have too little voice in what is done Nevertheless, the prospects for radical changes in the medical course are more hopeful than they have ever been I hope that the systematic lecture course of 80–100 lectures will disappear, and that the time gained will be mainly used to give the students more time with their patients, from whom I believe they will in the long run learn more than from their teachers

This does not mean a smaller teaching load on staff, but a diversion of their time from formal lecturing to giving clinical *tutorials* and *supervising* the work of students in the wards Trial could be made of mixed firms of 4 senior and 4 junior medical and surgical clerks, in which the seniors would be responsible for note taking and would go on staff rounds, while the juniors would be coached in physical signs and in history taking, both by staff and by the senior students Students are much better deployed in small responsible groups than in *masses* of passive listeners

THE SPIRIT OF A MEDICAL SCHOOL

There is general agreement, though with some variation in emphasis, that we have to provide both an education and a technical training In the first of these, *the emphasis is on drawing out* the student's own latent processes of thought and expression, in the second on handing on to him those practical courses of action which are appropriate *to our* present understanding of patients and their diseases Because of human frailty, the time devoted to technical training—a relatively simple matter—tends always to encroach on the time available for education In the last result, the student probably has to educate himself by discussion with his colleagues and teachers, by hearing his teachers discuss patients, by his own observations on patients, and by reading outside the student textbooks Such activities are refractory to planning, although something can be done by arranging discussion classes, sometimes with members of different departments, at which attendance is voluntary More important, however, is the provision of time for those activities which *cannot* be planned from above Negatively, this means *that* we must not fill up the student's days, weeks, and *months* with organised programmes Positively, it means that teachers must always be willing to respond to inquiries which may be ill phrased or based on ignorance, it is far too easy to get a cheap laugh from the rest of the class, and so ensure that that student will never ask you a question again Teachers must be willing to discuss diagnosis and treatment with their colleagues in the presence of students, without the short-cut of authoritarian pronouncements In Manchester, our curriculum has been modified to allow students at least one summer vacation in their clinical years, how they use this time is ultimately at their own discretion, though the dean of clinical studies gives advice and help on clinical opportunities in non-teaching hospitals

In so far as we liberate the curriculum in such ways, we are taking a chance on the initiative and self-discipline of our students For the man who demands passive instruction, the free time which we provide will be given over to textbooks, or even wasted On the other hand, the man with initiative will be able to spend more time in the wards, to see what goes on in other hospitals or in general practice, or even to take part in investigation, if his interests lie that way This is the kind of activity which goes on in the best American schools It would be foolish to extrapolate from the leaven to the lump, but I was tremendously impressed by the way in which students were an integral part of the hospital service and able to discuss things freely with the staff This is partly a matter of the staff being very numerous, so that each of them had far less "routine" clinical work than would be usual over here, but the general spirit of inquiry and discussion was obvious, nor was this achieved at the expense of careful clinical work I would agree with almost all the points made by Bauer,[1] describing the American system from the inside; my chief reservation would be that the "on and off service" arrangement is not compatible with our present ideas of a continuing relationship between a physician and his patient While the alternation of teachers may benefit the students, the alternation of physicians is less closely in the patient's interests, unless of course it is made at his own or his doctor's request

"FINALLY"

It has not escaped me that these reflections do not contain any definite plan for a medical curriculum While I am bold enough to have opinions on the general principles of curricular reform, my audacity stops short of describing the syllabus for a medical course in my private utopia Rather, I have drawn attention in no very original way to problems which will be discussed in the next year or two by medical teachers in the different schools, their formal solution is a task for medical faculties, acting in such concert as they may achieve To colleagues on my own faculty I owe a debt which cannot be assessed, let alone repaid, but they have no responsibility for these reflections, and I doubt if any of them would agree with all the opinions I have voiced I have a more clearly defined obligation to the Wellcome Trust, who made it possible for me to visit the medical schools at Johns Hopkins, Columbia and Harvard, and to the teachers in these schools who so willingly explained their beliefs and practices

Finally, I should emphasise that my criticisms of present institutions are not to be construed as support for a radical re shuffling of the medical course, such as has been in progress at Cleveland, I have not witnessed this far-reaching experiment, but have heard reports that the pressure of formal teaching, although it is cast in a different pattern is as heavy on the student there as elsewhere, and more so on the staff, so that they have less time for original work Moreover, I am not maintaining that in this country we have any need to feel ashamed of our general standard of medical practice or teaching, by comparison with other countries I have little patience with bitter statements that medicine "has been ruined as a career," and that we have "lost our professional freedom", I know of no other qualification which opens the door to so many different and interesting ways of spending one's life as a degree in medicine

Medicine and the Law

Under the Influence of Insulin

THE Divisional Court of the Queen's Bench Division allowed this appeal from a decision by justices dismissing charges under the Road Traffic Act, 1930, brought against a diabetic driver

A pharmaceutical chemist who had had diabetes for 12 years was charged before the justices with unlawfully driving a motor car (1) when under the influence of a drug to such an extent as to be incapable of having proper control of the vehicle, contrary to section 15 (1) of the Road Traffic Act 1930, (2) without due care and attention, and (3) without reasonable consideration for other persons using the road, contrary to section 12 of the same Act The justices found that on Aug 13, 1956, after taking by injection his usual and prescribed quantity of 18 units of soluble insulin B D and consuming a regulated meal, the defendant drove his motor-car to a cinema, arriving at 6 40 P M At about 9 P M he left the cinema, unaccompanied, and remembered no more than walking down the entrance steps In fact he got into his car and drove it along a road for about four miles, when the car left the road, went through a hedge into a field, and stopped in gear He was discovered at about 10 15 P M sitting rigidly at the wheel but in a semicomatose state He was taken to hospital and found to be in a hypoglycæmic coma due to the over action of the insulin injection taken earlier

It was contended for him that on the medical evidence before the justices the taking of insulin was not the taking of a drug but the replacement of an essential hormone which his body mechanism was unable to secrete, and of which it was therefore totally deficient, and that he was not therefore under the influence of a drug within the meaning or contemplation of section 15 (1) of the Act of 1930, and that being totally unaware that he was driving a motor car he could not be guilty of the offences with which he was charged under section 12 The justices dismissed the charges The prosecution appealed to the Divisional Court of the Queen's Bench Division

The LORD CHIEF JUSTICE said that insulin was clearly a drug for the purposes of the Act of 1930 He thought that a drug meant a medicine or medicament given to cure or alleviate or assist an ailing body No doubt a person taking insulin was taking a drug in the sense of a medicine, but this was a clear case which should go back to the magistrates, who should remember that section 15 was designed for the protection of the public, and if people were in a condition of health which either of itself rendered them liable to go into a coma, or the remedies for which might send them into a coma, they must not drive, because of the danger that would result to the rest of Her Majesty's subjects

Mr Justice CASSELS, agreeing said that he would define "drug" as a substance used as a medicine It would be no consolation to anybody who might unfortunately be injured by a person when driving under the influence of a drug to be told "It was not my fault because I was under the influence of a drug"

Mr Justice LYNSKEY, also concurring, said that under section 15, if it were proved that (*a*) the person accused was driving or attempting to drive a motor vehicle on a public road and (*b*) that he was under the influence of a drug to such an extent as to be incapable of controlling the vehicle, the justices were compelled to convict On the ordinary definition his Lordship thought that insulin was, and was to be treated as, a drug mode of thought as well, but the third type of mental activity, which embraces the practical application of the first two, would scarcely be included in any reasonable definition of science Moreover, the planning of scientific observations and experiments is itself an art These various activities of the mind may require isolation for purposes of discussion, but this is an artificial process, and an education based exclusively on one of these types of mental activity would be grossly incomplete

---

[1] Bauer, W *Brit med J* 1956 ii 1443

Again, the distinction between a "practical" and an "academic" education means very little, at least to me I may not be understanding the issues involved, but "know-how" is scarcely of value unless attended by "know-why" and "know-when" It is a witless task to ascribe priority as between theoretical knowledge and practical skill, for the one cannot get along without the other At times, the right action may be inaction (*fortunately*, it was an American who composed the guileful epigram—"Don't just *do* something, John *stand* there") If medical practice were made up of eternally valid stereotypes of procedure, it could be taught by rule-of-thumb methods, but we all know that in medicine, as in life, the problems encountered are infinitely various, providing the truthful component of that veteran cliché "Each case must be judged on its merits" *It* seems plain that a medical training must inculcate both knowledge of currently accepted practical routines, and an ability to depart from or modify them in new situations

SELECTION OF STUDENTS

At the age when most students in this country apply for entry to medical school, they are in *practice*, if not in theory, selected largely on the basis of their showing in General Certificate of Education (advanced level) Reports from headmasters would often be of great value (positive or negative) if the headmaster himself were the applicant, but in assessing the students, with honourable exceptions, they are less helpful The 10–15 minutes' interview gives a few applicants an opportunity for self-elimination, and others give evidence of great promise, which may even be fulfilled, but the findings at interview rarely deviate from those predictable on examination results More elaborate selection procedures have been described, but there is no solid evidence that their results justify the added load on teaching staff The main defect of selection by G C E results is the admission of the occasional student who can reproduce the input of intensive coaching, but who cannot learn for himself in a university. (I am not being cynical about this in the long run, we must be able to teach ourselves, and to criticise what others teach us, and if a university encourages us to do this, it is doing its job) The American medical schools seem to me to have an advantage here, in that their applicants have already had their chance to prove themselves under university-type conditions for three years, so that the selecting school has more to go on, and there may be less compunction in rejecting people who at least have a modest college degree than in excluding people who have done badly in anatomy and physiology If the "premedical subjects" are used as a screen, we run the risk of excluding otherwise adequate students who have had no satisfactory schooling in science, and are merely slow in coming to terms with it

CONTENT OF THE MEDICAL CURRICULUM

The present medical curriculum is a sort of Christmas tree, in which a conventional basic structure (common to all schools, stereotyped by regulation, and scarcely altered since 1900) has been decorated with tinsel and fairy lights (varying from school to school, and reflecting the localised enthusiasms of teaching staff) There has been much criticism, and this has very properly been based on the burden which such a curriculum lays on the medical student The outstanding *student* can take it but his less gifted colleague, even if he scrapes throug all the examinations, becomes dispirited by the mas of factual information I am *quite unashamedly* with the pruners rather than with the decorators, and thre changes in the past year or two seem to me to enhanc the case for vigorous pruning

The first two are the compulsory postgraduate yea and the increasing recognition that "general practice" needs some measure of postgraduate training as much as any "specialty" These *two things seem* to me t legitimise something which has in any case come abou from the pressure of events—that the student no longe leaves us fully armed against all medical contingencie (did he ever do this ?), and *that* we *on our* part need not lie awake at nights if he should slip through ou meshes ignorant of the insertions of certain muscles, the posology of each of the *British Pharmacopœia* prepara tions of mercury, or even of the factors governing sodium reabsorption in the renal tubule

Thirdly, in the past year, the curriculum committe of the General Medical Council has made recommenda tions which are permissive, and no longer restrictive If these are accepted by the council, the individua schools will have the responsibility and opportunit of planning a course which may allow students to thin and do more, and sit and suffer less

The task of refining the content of the medical cour will be long, and the result will itself require revision as the years speed past Sectional interests will impede the process, and the ultimate beneficiaries, the students, will probably have too little voice in what is done Nevertheless, the prospects for radical changes in th medical course are more hopeful than *they* have eve been I hope that the systematic lecture course of 80-100 lectures will disappear, and that the time gained wil be mainly used *to* give the students more time with thei patients, from whom I believe they will in the long ru learn more than from their teachers

This does not mean a smaller teaching load on staff, but a diversion of their time from formal lecturing t giving clinical tutorials and supervising the work o students in the wards Trial could be made *of* mixed *firms of 4 senior and 4 junior medical and* surgical clerks, in which *the* seniors would be responsible for note taking and would go on staff rounds, while the juniors would be coached in physical signs and in histor taking, both by staff and by the senior students Student are much better deployed in small responsible group than in masses of passive listeners

THE SPIRIT OF A MEDICAL SCHOOL

There is general agreement, *though* with some varia tion in emphasis, that we have to provide both a education and a technical training In the first of these, the emphasis is on drawing *out* the student's own latent processes of thought and expression, in the second on *handing on to him those practical courses of* action which are appropriate to our present understanding of patients and their diseases Because of human frailty, the time devoted to technical training—a relativel simple matter—tends always to encroach on the time available for education In the last result, the student probably has to educate himself by discussion with his colleagues and teachers, by hearing his *teacher* discuss patients, *by* his own observations on patients, and by reading outside the student textbooks Such activities are refractory to planning, although something can be done by arranging discussion classes, *some* times with members of different departments, at which attendance is voluntary More important, however, is the provision of time for those activities which cannot be planned from above Negatively, this means that we must not fill up the student's days, weeks, and *months* with organised programmes Positively, it means that teachers must always be willing to respond to inquiries which may be ill phrased or based on ignorance, it is far too easy to get a cheap laugh from the rest of the class, and so ensure that that student will never ask you a question again Teachers must be willing to discuss diagnosis and treatment with their colleagues in the presence of students, without the short-cut of authoritarian pronouncements In Manchester, our curriculum has been modified to allow students at least one summer vacation in their clinical years, how they use this time is ultimately at their own discretion though the dean of clinical studies gives advice and help on clinical opportunities in non-teaching hospitals

In so far as we liberate the curriculum in such ways, we are taking a chance on the initiative and self-discipline of our students For the man who demands passive instruction, the free time which we provide will be given over to textbooks, or even wasted On the other hand, the man with initiative will be able to spend more time in the wards, to see what goes on in other hospitals or in general practice, or even to take part in investigation, if his interests lie that way This is the kind of activity which goes on in the best American schools It would be foolish to extrapolate from the leaven to the lump, but I was tremendously impressed by the way in which students were an integral part of the hospital service and able to discuss things freely with the staff This is partly a matter of the staff being very numerous, so that each of them had far less "routine" clinical work than would be usual over here, but the general spirit of inquiry and discussion was obvious, nor was this achieved at the expense of careful clinical work I would agree with almost all the points made by Bauer,[1] describing the American system from the inside, my chief reservation would be that the "on and off service" arrangement is not compatible with our present ideas of a continuing relationship between a physician and his patient While the alternation of teachers may benefit the students, the alternation of physicians is less closely in the patient's interests, unless of course it is made at his own or his doctor's request

"FINALLY"

It has not escaped me that these reflections do not contain any definite plan for a medical curriculum While I am bold enough to have opinions on the general principles of curricular reform my audacity stops short of describing the syllabus for a medical course in my private utopia Rather, I have drawn attention in no very original way to problems which will be discussed in the next year or two by medical teachers in the different schools, their formal solution is a task for medical faculties, acting in such concert as they may achieve To colleagues on my own faculty I owe a debt which cannot be assessed, let alone repaid, but they have no responsibility for these reflections, and I doubt if any of them would agree with all the opinions I have voiced I have a more clearly defined obligation to the Wellcome Trust, who made it possible for me to visit the medical schools at Johns Hopkins, Columbia and Harvard, and to the teachers in these schools who so willingly explained their beliefs and practices

Finally, I should emphasise that my criticisms of present institutions are not to be construed as support for a radical re-shuffling of the medical course such as has been in progress at Cleveland, I have not witnessed this far-reaching experiment, but have heard reports that the pressure of formal teaching, although it is cast in a different pattern is as heavy on the student there as elsewhere, and more so on the staff, so that they have less time for original work Moreover, I am not maintaining that in this country we have any need to feel ashamed of our general standard of medical practice or teaching, by comparison with other countries I have little patience with bitter statements that medicine "has been ruined as a career," and that we have "lost our professional freedom", I know of no other qualification which opens the door to so many different and interesting ways of spending one's life as a degree in medicine

Medicine and the Law

Under the Influence of Insulin

THE Divisional Court of the Queen's Bench Division allowed this appeal from a decision by justices dismissing charges under the Road Traffic Act, 1930, brought against a diabetic driver

A pharmaceutical chemist who had had diabetes for 12 years was charged before the justices with unlawfully driving a motor car (1) when under the influence of a drug to such an extent as to be incapable of having proper control of the vehicle, contrary to section 15 (1) of the Road Traffic Act 1930, (2) without due care and attention, and (3) without reasonable consideration for other persons using the road, contrary to section 12 of the same Act The justices found that on Aug 13, 1956, after taking by injection his usual and prescribed quantity of 18 units of soluble insulin B D and consuming a regulated meal, the defendant drove his motor-car to a cinema, arriving at 6 40 P.M At about 9 P.M he left the cinema, unaccompanied, and remembered no more than walking down the entrance steps In fact he got into his car and drove it along a road for about four miles, when the car left the road, went through a hedge into a field, and stopped in gear He was discovered at about 10 15 P M sitting rigidly at the wheel but in a semicomatose state He was taken to hospital and found to be in a hypoglycæmic coma due to the over action of the insulin injection taken earlier

It was contended for him that on the medical evidence before the justices the taking of insulin was not the taking of a drug but the replacement of an essential hormone which his body mechanism was unable to secrete, and of which it was therefore totally deficient, and that he was not therefore under the influence of a drug within the meaning or contemplation of section 15 (1) of the Act of 1930, and that being totally unaware that he was driving a motor car he could not be guilty of the offences with which he was charged under section 12 The justices dismissed the charges The prosecution appealed to the Divisional Court of the Queen's Bench Division

The LORD CHIEF JUSTICE said that insulin was clearly a drug for the purposes of the Act of 1930 He thought that a drug meant a medicine or medicament given to cure or alleviate or assist an ailing body No doubt a person taking insulin was taking a drug in the sense of a medicine, but this was a clear case which should go back to the magistrates, who should remember that section 15 was designed for the protection of the public, and if people were in a condition of health which either of itself rendered them liable to go into a coma, or the remedies for which might send them into a coma, they must not drive, because of the danger that would result to the rest of Her Majesty's subjects

Mr Justice CASSELS, agreeing said that he would define "drug" as a substance used as a medicine It would be no consolation to anybody who might unfortunately be injured by a person when driving under the influence of a drug to be told "It was not my fault because I was under the influence of a drug"

Mr Justice LYNSKEY, also concurring, said that under section 15, if it were proved that (*a*) the person accused was driving or attempting to drive a motor vehicle on a public road and (*b*) that he was under the influence of a drug to such an extent as to be incapable of controlling the vehicle, the justices were compelled to convict. On the ordinary definition his Lordship thought that insulin was, and was to be treated as, a drug

The Hospital Doctor's Unprotected Belongings

A doctor was employed by a hospital management committee at a remuneration of £425 a year with a deduction of £125 "in respect of board, lodging and other services provided" He lived in a hostel near the hospital, and came back one night to his room to find that a number of personal effects had been stolen He brought an action in the county court for the loss, claiming against the management committee that they owed him a duty that they would take reasonable care of his bedroom, personal effects, and the keys to the doors, or alternatively that there was an implied term in his contract of employment that they were under the same duty By their defence the committee denied that they owed any duty of care to him The county court judge held that the committee was not under any duty of care The doctor appealed, his counsel stating that the case was supported by the Medical Defence Union and was a test case in the sense that this was one of three similar thefts

Lord Justice HODSON said that from one point of view the house officer's salary was £425 and from another was £300 plus board and lodging valued at £125 The county court judge had accepted the committee's general proposition of law that there was no duty on the occupier of premises to safeguard against theft the chattels of an invitee by a third person who came on to the premises There were exceptions to that general rule in the case of guest houses or boarding-houses which people carried on as a business for gain, they had to take some care of the goods of their guests But the duties of boarding-house keepers could not possibly be said to arise in the present case The management committee was not carrying on a boarding-house but keeping this hostel for the benefit of the staff, just as if the staff were resident in the hospital building itself and getting their food and lodging free This was simply a case of master and servant where the master paid the servant partly in cash and partly by giving him food and lodging The house-officer did not make any separate payment for what was provided It was simply deducted from his pay and he received the net sum in the same way as would a domestic servant who lived in and got her keep In Deyong *v* Shenburn [1946] 1 K B 227, Lord Justice du Parcq had said that there was no decision and no authority for the proposition that a master must, merely because of the relationship of master and servant, take reasonable care for the safety of his servant's belongings in the sense that he must take steps to ensure that no wicked person should have an opportunity of stealing the servant's goods Those words applied directly to the present case and were not confined to what were called "domestic servants" If that was right, this claim must fail

The only way in which the house-officer could succeed in his claim would be if he could show that such a term must be implied in the contract of employment On the facts as found and pleaded there was here no room for such an implication It would be going a long way if it were held that the intervention of a wicked person such as a thief should be insured against by masters employing servants in any capacity, and there would have to be a specific term in the contract or circumstances from which such a term must necessarily be implied before such a result could be reached

Lord Justice MORRIS, concurring, said that it would be quite unreal to say that the management committee were in any sense lodging-house keepers The house officer was presumably resident in order to be available at nearly all times at short notice The position was thus simply that of master and servant, with an obligation on the servant to live in the hospital That did not mean that somebody in the position of this doctor must be called a domestic servant, but merely that he had to live in the hostel just as a domestic servant would live in

Lord Justice SELLERS delivered a concurring judgment The appeal was dismissed

Public Health

Poliomyelitis Vaccine

IT is hoped that distribution of anti-poliomyelitis vaccine will begin again throughout England and Wales about the middle of this month

Supplies had been expected during January, but the vaccine has to satisfy stringent standards of purity and potency, and one large batch was rejected because there was evidence of slight contamination, though no live virus was found In another batch, one test must be re-done, and this will take about a fortnight

Sir John Charles, chief medical officer of the Ministry of Health, has explained the position in a letter to medical officers of health The next few issues of vaccine should, he said, be large enough to provide two injections each for about 200,000 further children aged 2–9 from those who registered last year for vaccination

The Midwifery Service

In his report for 1955 Dr William Sharpe, medical officer to no 16 division of Lancashire, *observes* that of the 1588 births in the division during the year 81% occurred in hospital Most mothers, he says, obviously prefer not to have their babies at home, but why this should be so is not easily ascertained

> "Is it that we are not sufficiently persuasive in pointing out the advantages of making the birth of a child a real family affair which it can be only at home? Or is the economic disincentive applied to home confinement too great? It seems that if this latter factor is the main one it might be offset a little by offering free, or at reduced rates, home helps during the lying in period This concession, though a little more costly to the Local Health Authority, would, if it had the effect of decreasing hospital admissions, be a considerable national saving for the health service"

In England Now

A Running Commentary by Peripatetic Correspondents

LAST Sunday, soon after the night nurses came on duty, the patient at the far end of the ward developed more pain and the house-physician was summoned Five minutes later, nineteen pairs of eyes watched curiously as he made his way down the length of the ward and back. He thought the patient too ill to have an operation and he telephoned his chief Twenty minutes later, all eyes turned as the physician, accompanied by his house-physician and the nurse, marched briskly to the far end of the ward He thought that an operation, although indicated, carried considerable risk and called in the surgeon To the inhabitants of a medical ward, the appearance of a surgeon is always regarded with grave misgivings, and all eyes were agog when the procession of four set out on the journey to the end of the ward some twenty minutes later In the opinion of the surgeon, the operative risk was negligible compared to the risk of the anæsthetic, and the anæsthetist was invited to express an opinion Soon after, a wakeful ward watched a quintet of specialists and auxiliaries on their pilgrimage to the last bed

Now anæsthetists, like spectators at a football match, are often inspired to a plan of action not readily apparent to the principal combatants Thus the anæsthetist opined that the risk of the operation depended on the result of a blood-test, and the pathologist was summoned. Twenty minutes later, he too ran the gauntlet of curious gazes as he negotiated the length of the ward Few pathologists, called in to help with a difficult case, can resist suggesting a further investigation The first blood-test was normal, but the result of the second made an immediate X-ray examination imperative

By this time, the area before the hospital main entrance was enough to set every National Health Service heart beating with pride In an imposing row stood the parked cars of as many members of the staff as could be seen on any weekday The physician's old Ford rubbed noses with the pathologist's A70, while the anæsthetist's Velox stood alone some distance away, because it was brand new And when the brilliant headlights of the radiologist's Jaguar swept through the drive, hospital history was made

The procession that entered the ward on its final journey brought a gasp of admiration from the two rows of figures sitting bolt upright in their beds With bulging eyes, the nineteen heads swivelled slowly through a full semicircle Gloriously, majestically, past went the consultants and specialists, the residents and nurses, and, bringing up a triumphant rear, the crane-like apparatus of the portable X ray, propelled by two porters

It took all of us exactly four-and-a-quarter hours to decide to do nothing that night

* * *

Our R S O has just got his fellowship Hearing himself called Doctor used to give him a bitter-sweet extrasystole in memory of all the examination hazards safely and astonishingly negotiated Now he feels the same lift of the emotions when addressed once more as Mister and regards the reassumption of a title common to most of his fellow men as a rare and delightful distinction He feels hurt when it is forgotten Perhaps the rules are a little difficult to grasp in our hospital Many of our patients think that all specialists should be Mister and whenever Doctor slips out it is corrected to Mister I mean A visiting American surgeon expected Doctor and we had been carefully coached in the fact that the qualifying examination "over there" is the M D One of our own surgeons has his M D , and one of our physicians, for some reason, has not At the same time as our R S O was promoted from Doctor to Mister, our biochemist, a science graduate, who has always been careful to inform newcomers that he is not a doctor, got his PH D

* * *

To the public at least, the significance of the surgeon s CH M , or M CHIR , or M S is little known Perhaps they would be better informed if it were used more conspicuously with "Master of Surgery' after it in parenthesis Two things then might happen Probably some people would regard the surgeon as being addressed as Mister by virtue of being a Mister of Surgery , but others would address him by his true title of Master This innovation would be agreeable Now that Master is less used in the nursery, few surgeons should greatly object to sharing the title with the head of Balliol College or some of the elder sons of the Scottish peerage

* * *

Full fathom five lay the father of all pike in England's loveliest lake Not that he was a serious competitor to the sportsmen flicking their trout-flies from the shallows, it was much more serious than that He was cruising over my favourite larder, the dark layers of ice-cold water between 50 and 70 feet, where waiting for our delectation are those arctic lovelies the char

If the name of char or *Salvelinus willoughbyi* means nothing to you, indeed the loss is yours Some fine spring day you should come and see for yourself that the polar ice-cap has receded from Cumbria Otherwise you may pass to dust without being tranquillised by the soothing vortices gliding away from your oars as you row slowly between wooded slopes, the tinkle of the bell on your trolling tackles, and the call to action You may be denied the breathtaking sight of a spawning char, vivid red belly and emerald green back glistening with the brilliance of enamel for the few fleeting moments ere corruption starts before your eyes The frailties of human flesh may keep you and me off the water, but we can still solace ourselves on the fishmonger's slab The pink delicacy of char lies somewhere between salmon and trout, and not nearly so dear to buy , it has the vicarious piquancy of lamp and gaff without the risks

That was why the char and I took a very dim view of the pike down there Maybe a little self-centred in our outlook, we each made out plans for survival, limited in the chars' case vis-a-vis the pike They retired to the basement while the local experts set some large-mesh nets Both parties waited with interest for a couple of weeks before patience was rewarded At twenty-six pounds our pike tipped the scale, and there were a couple of fine char inside him Justice was satisfied by converting his mighty bulk into cookable steaks When it comes to stuffing specimens, around our way we believe that charity begins at home—an elementary rule of survival which gives us the strength to catch some more

* * *

After watching a television programme last night I was so irritated that I sat down and wrote myself this letter

Dear Doctor,

Please sign my family s cards as I want to change my doctor like Christopher Mayhew said I should on the television All that happens when I see you is we talk and talk about my nerves and you do nothing for me I want to go to the hospital for proper treatment and I won't have to do anything about getting better myself Perhaps they will give me a bottle of nerve tonic too like I said I needed

Truly yours,

N E PATIENT

* * *

We were visiting one of those admirable hospitals which have grown up by unplanned accretion from a cottage hospital and now carry the load of a population of 100,000 or more Matron asked if we would like to see the nurses' home It was not on our programme but she was so charming that, noses dripping, we hurried across the windswept plateau to the usual mid-Victorian ex-rectory designed by Nature to be the nurses' home of those admirable hospitals which have grown up by unplanned &c , &c As we opened the door of a small sitting-room, two young and pretty probationers sprang to their feet in some confusion, one of them dropping the book she was reading My companion said as he picked it up—rashly I thought—"Well, nurse what have you been reading ? " "And what do you think it was ? ' I asked the friend to whom I was telling the story "Oh Plato's *Republic*, I expect," he answered It was

Letters to the Editor

"DOCTOR"

Sir,—May I congratulate Doctor George Graham on his delightful article last week? How kindly he refers to the inverted snobbery which makes many surgeons insist on being called Mister—a proper title for the mate of a sailing ship, but to a surgeon, a reminder of a humbler origin than his brother physician In Dublin it is interesting to read on the plates on doors in Fitzwilliam Square and elsewhere where consultants practise, Surgeon So and so How very sensible!

Dr Graham correctly says that the curious practice does not exist in other countries except in those Dominions of the British Commonwealth which follow the practice of the Royal College of Surgeons But even in those countries the custom is by no means universal thus in Australia while there are some surgeons in some States who like to be called Mister, many prefer Doctor

May Dr Graham's hope be realised and in time this curious survival, reminiscent of the barber surgeons, cease Surely we should be proud to belong to the profession of doctors Please call *me* Doctor

Surgical Unit,
Cardiff Royal Infirmary

LAMBERT ROGERS

Sir,—Dr Graham wonders why fellows of the Royal Colleges of Surgeons prefer to be called Mister He might be interested in an explanation which I read or heard, I know not where, some little time ago

Most of the universities conferring the degree of doctor of medicine also confer a parallel degree of master of surgery, M S, or CH M The proper form of address for the holder of such a degree is surely Master, or the popular form, Mister Is it perhaps the wish to draw a parallel between this degree and the fellowship of the Royal Colleges that prompts the fellows to adopt the appellation Mister?

Aberdeen University

GEORGE L CHALMERS

TOWARDS PREVENTING SUICIDE

Sir,—Well might the Rev Edward Young exclaim in the year 1742 "O Britain infamous for suicide!" (Jan 26, p 203) Up to 1823 it was legal (and it was done in June of that year) to bury suicides at crossroads with a stake through their bodies, and up to 1870 the Crown had the right (though latterly it was not exercised) to confiscate the personal estate of a person dying by his own hand

DEATHS FROM SUICIDE, ROAD ACCIDENTS, AND HOMICIDE
(1948–51)

Country	Death rate (per 100 000 persons)			
	Suicide	Road accidents	Homicide	Suicide + road accidents + homicide
Switzerland	23 5	12 7	1 0	37 2
Denmark	23 3	7 8	1 3	32 4
Austria	22 7	5 5	1 4	29 6
Western Germany	18 2	15 4	1 0	34 6
Japan	17 5	2 2	2 1	21 8
France	15 2	2 5	0 6	18 3
Sweden	14 9	7 0	0 6	23 4
Belgium	13 6	10 1	1 3	25 0
U S A	11 2	22 1	5 8	39 1
South Africa	11 1	15 2	2 9	29 2
England and Wales	11 0	8 4	0 5	19 9
Australia	9 3	21 6	1 0	31 9
New Zealand	9 2	11 8	1 1	22 1
Canada	7 7	16 8	1 3	25 8
Norway	7 4	3 7	0 4	11 5
Israel	7 1	6 5	0 9	14 5
Italy	6 8	9 6	1 5	17 9
Holland	6 2	7 4	0 3	13 9
Scotland	5 7	9 0	0 3	15 0
Spain	5 4	1 3	0 8	7 5
Chile	4 8	1 2	10 2	16 2
Northern Ireland	4 2	9 7	0 2	14 1
Eire	2 7	4 8	0 2	7 7
Columbia	1 3	5 7	28 7	35 7

I doubt, however, whether the reverend gentleman would wish to reproach us over the present (1948–49) suicide-rates, the table shows that, of the 24 countries, England and Wales ranks 11th, with Scotland, Northern Ireland, and Eire ranking 19th, 22nd, and 23rd

Since you, Sir, called attention to the fact that prevention of fatal road accidents attracts more public attention with us than prevention of the (latterly) more numerous suicides (Jan 26, p 206), I have given rates for these, and, for the benefit of students of the polar character of suicide and homicide, those for homicide[1]

The aggregate mortality-rates for suicide plus road deaths plus homicide are highest in the United States and Switzerland, and lowest in Spain and Eire

Isleworth, Middlesex

H PULLAR STRECKER

Sir,—The article by Dr Parnell and Dr Skottowe (Jan 26) deserves the closest attention, but I think it is unfortunate that they give the impression that suicide can only be prevented, and depression treated, by admission to a mental hospital A large number of depressed patients is now being successfully treated by means of electroconvulsive treatment, modified by relaxants, in outpatient clinics of general hospitals Most of the mental hospitals, at least in the London area, are overcrowded, often there is a considerable delay, amounting in some cases to several weeks, before a bed can be obtained The patient may well commit suicide during this waiting period Outpatient treatment, on the other hand, can usually be arranged immediately and with the willing cooperation of the patient—which is not always so readily forthcoming when admission is proposed

There are, of course, cases where the suicidal risk is too great to permit the patient to remain at home, but the clinical judgment of an experienced psychiatrist can usually be relied on to decide which method of treatment should be adopted There is much to be said in favour of keeping patients at home,-apart from the shortage of mental hospital beds and mental nurses, and the cost of inpatient treatment

London W 1

J C SAWLE THOMAS

Sir,—It is good to see Dr Parnell and Dr Skottowe ventilating the subject of suicide, particularly among students in universities, and one is grateful to them for emphasising the importance of direct questioning of depressed or anxious patients on this matter I have more than once established a sound relationship with such a person and produced relief by anticipating the student's confession and expecting the temptation to suicide to be present I am therefore the more surprised to see these physicians so strenuously recommending the admission of patients to hospital on this sign alone I wonder whether I have misunderstood them, but I was once similarly surprised by the attitude of a consultant psychiatrist who, after seeing and talking in a friendly way with a depressed patient of mine about the suicidal situation that he was in, said to me, "Did you see how that man talked to me as though we two understood one another in this matter? He is dangerously suicidal and should be in hospital" I can see that for therapists with hospital beds readily available, admission may offer the best solution, but surely for the general practitioner the need for admission recedes in proportion to the increase of understanding of the position achieved between patient and therapist

I was visited early one summer morning by a distraught young man who, in an exaggerated manner, was working through an early pattern of panic at examinations He had had no sleep at all that night In the course of half an hour I heard a good deal of hatred poured out upon both his parents, whom he felt to be pushing him along a path he could not take Then suddenly he blurted out "At one o'clock in the night I mixed myself a glass of thirty aspirin tablets I had it beside me on the table" I reacted with, 'That would have 'taken it out' of the people you hate so much, I suppose," and he said quickly, "Yes, I thought it would serve them jolly well right" He was aware of a powerful suicide deterrent in his loving a girl who loved him, but I think he had been less aware before our talk of the hate motive which had been tempting him to suicide and I hope that the conscious emphasising of it by both of us will stand him in good stead if the situation ever recurs, particularly if there should be less help from the girl

---

[1] United Nations, Demographic Yearbook. New York, 1953, table 12

It is sometimes necessary to explain to a confused and careless student that his apparently unaccountable behaviour springs from suicidal urges of which he has been unaware I am thinking of absent-minded people who expose themselves to traffic dangers, and foolhardy folk who take inordinate risks in their adventures with the elements, on mountains, in caves, or over the sea A proper wariness of his own weakness on this score can greatly help a person to avoid damage Where one cannot find acceptance of the inner threat, as in a patient who assured me repeatedly that she took eighteen carbromal tablets all at once simply to get a good night's sleep, one is safer to assume serious, if not psychotic, disturbance, but it is very hard to persuade such a person to be admitted voluntarily

I doubt whether any depressed person has no suicidal inclinations, and young men and women suffering their first attacks of this torturesome complaint need very careful attention, if only to support them until they have learned to manage their own condition A bond of real affection can work miracles, but it is difficult to forge

The older person, particularly the physician, needs to take herself or himself to task lest anxieties with regard to patients are in too great part projected from inside the observer Which of us has not, in our fantasies, done rather more than just to long for release from difficulty, for oblivion, for perpetual sleep, for death itself? It is not given to all of us all the time to see life as ever lasting challenge We must therefore be afraid of suicide in others as in ourselves Let us sustain one another, face risks together, and pray that we be kept from panic

Students' Health Service,
University of Bristol
AGNES WILKINSON

SIR,—The article by Dr Parnell and Dr Skottowe is most valuable and will cause most of us general practitioners deep and helpful searching of heart The important omission, however, to my mind, is the lack of any mention of the relationship of alcoholism to suicide Often this connection is not made public at inquests, just as often the true state of affairs is not realised by the family or even by the family doctor

When will we come seriously to grips with this vital and tragic problem?

Bewdley Worcs
G S LAWRENCE

THE REMUNERATION CLAIM

SIR,—Last week I attended a meeting held under the auspices of the local branch of the B M A at which the remuneration dispute was discussed

I was amazed and shocked by the views expressed by the convener of the meeting and by many members of the audience What the association advocates, if the claim fails, really amounts to strike action, although some prefer to call it resignation from the service Whether called "strike" or "resignation" it is really nothing but shameless blackmail, since, as one member of the B M A pointed out such action would cause a crisis A special point was made of the Government's moral obligation towards the profession, but it seems hardly right for doctors to insist on the moral aspect if they intend to follow trade-union tactics and add yet another crisis to the long series of miserable strikes, and thus forfeit what little is left of public sympathy for the medical profession

Brighton
NOEL ALDER

POST-GASTRECTOMY BILIOUS VOMITING

SIR,—There is no doubt that the method of investigation of bilious vomiting presented by Mr Scott and Dr Whiteside (Dec 29) is extremely valuable Bilious vomiting is an annoying and at times a disabling condition, and it is hoped that many cases will be investigated by this method in the future, so that a true conclusion can be reached

One of us (G R A) started using this technique in 1954, and since then we have used it in over 50 cases to demonstrate the afferent loop in these post-gastrectomy disorders The afferent loop is shown best, whether there is stasis or not, *before* the gall-bladder is caused to contract A film taken two hours after injection of 'Biligrafin' and while the patient is still fasting is optimal After food has been taken and the gall bladder has contracted, the fine contrast pattern of the normal afferent loop is lost The films should always be taken with the patient erect, as the effects of afferent loop stasis are shown to the best advantage in this position The afferent loop tends to empty (in the absence of physical obstruction) in the supine position

Our observations suggest that distension of the gall bladder is not a factor in bilious vomiting In nearly all cases of 70% gastrectomy, the vagal fibres to the gall bladder are divided, and the gall bladder function thereafter follows the features so clearly described by Johnson and Boyden.[1] They showed that complete severance of vagal fibres results in progressive enlargement of the gall-bladder Under no other conditions does such a rapid increase in size occur Vagotomy, however, does not affect the rate of evacuation of the gall bladder after a fatty meal They suggest that the vagi control the tone of the gall bladder while the evacuating mechanism is probably under hormonal influences It may be that the interdigestive size of the gall-bladder is a good test to see whether the vagal fibres have been divided Certainly in nearly all, if not all, the cases of gastrectomy we have reviewed, the gall bladder is distended in this way As only a few of these patients had bilious vomiting, it is unlikely that gall bladder distension per se is a factor In a patient seen this week who had a Polya gastrectomy ten years ago, severe and intractable bilious vomiting has recently started, even though his gall bladder was removed five years ago Sometimes the gall bladder is shown grossly distended after gastrectomy even when it contains gall stones, in one case where the gall bladder was removed for such stones, the bilious vomiting persisted Our findings in these cases suggest that the bile pools, either in the gastric remnant or in the efferent loop We have some doubts, therefore, whether anastomosis of the gall bladder to the efferent loop will really cure the condition. We agree, however, that distension of, or stasis in, the afferent loop does not appear to be a necessary accompaniment of bilious vomiting

Unfortunately, the clinical manifestations of this condition do not suggest an easy answer Some patients vomit the bile after food and some before In some cases it appears immediately after the gastrectomy and clears up within a year, in others it does not come on for two, three, or even ten years after operation, and can then be very severe Some cases vomit bile every day, and others have attacks lasting two or three days, after which the condition will remit for a week or more In many cases, lying down will clear the condition, this fits in with the observation that the biligrafin-loaded bile which pools in the efferent loop will pass on when the supine position is adopted T J Butler (personal communication 1951) made the interesting observation that the condition was twice as common in the right to left as in the left-to-right anastomosis We have been unable to find figures of other observers on this point

---

[1] Johnson F E Boyden E A *Surgery* 1952 32 591

To us it appears that the afferent loop in these cases is usually normal as shown by this technique, why the biliary fluid is held up in the gastric remnant or efferent loop in some cases, and not in others, remains an unsolved problem

Southmead Hospital,
Bristol

W M CAPPER
G R AIRTH

SIR,—We have read with great interest the article by Mr Scott and Mr Whiteside, for we, too, have investigated gall bladder function after gastrectomy[1] Nine patients were studied, before and after gastrectomy, by intravenous cholecystography and duodenal drainage The following results were obtained

1 In four patients who had had Polya gastrectomy, gall bladder function was normal

2 In three patients who had had total gastrectomy and œsophago jejunostomy the gall bladder was enlarged and insufficiently contracted after the test meal

3 In two patients who had had total gastrectomy and œsophago duodenostomy or œsophago jejunostomy, visualisation of the gall bladder was impossible despite repeated examination

Duodenal drainage revealed continuous bile-flow, and detection of the A, B, and C fractions of the bile was absolutely impossible in all this group of patients

It is our impression that all types of gastrectomy alter the function of the gall-bladder In the Polya type gastrectomies, these changes are rather slight, but in total gastrectomy the functions of the gall-bladder are much altered

RETURN TO PLANNING

SIR,—May I commend your leading articles on Psychotherapy in General Practice (Dec 29) and on Return to Planning (Jan 5) and Dr Hopkins's highly relevant letter (Jan 5)?

Dr Hopkins's plea for some special fee for psychotherapeutic sessions, such as is already provided for obstetrics under the National Health Service, might be extended to other lengthy procedures, thus encouraging general practitioners to lift some of the load off hospital staffs and add variety to their repertoire

The larger part of general practice consists in numerous small services—i e, those requiring little time but not necessarily of little importance The remainder consists in a small number of relatively lengthy procedures Too many patients and a pure capitation-fee system tempt even the best doctors at times to unload the latter on to hospitals. To maintain that we are purely economically motivated is cynical nonsense, but surely there is no harm in making our financial arrangements encourage in the long run the general trend we want to produce The capitation fee achieves this with respect to the "numerous small services" part of general practice, by encouraging the doctor to give satisfactory long-term care to a family in order to retain them on his list, without the temptation to press needless services on them as a pure fee for service system may My admittedly brief but enjoyable experience of general practice in Britain under the N H S and in Canada under fee for service health insurance persuades me that some such combination of the capitation fee and fee-for-major-services would be the ideal The Canadian system is superior in encouraging doctors to undertake major procedures, but is wasteful of time, money, and clerical work when applied to the many minor services

A G RICHARDS

MÉNIÈRE'S DISEASE

SIR,—In your leader on this subject (Jan 26) you say that Lewis and Harrison found that injection of the stellate ganglion was not a success in treating the attacks of giddiness present in this condition Lewis and Harrison, however, do not claim to have injected a patient *during* an acute attack

In my experience, injection of the appropriate stellate ganglion is the treatment of choice for an acute attack Having seen the effect of an immediate block in six patients, with dramatic improvement in their symptoms I am convinced that this measure is of great value If successful, it should be followed up by regular vasodilator drug therapy until the patient is fit enough for thorough investigation and decision as to the future means of treatment

Immediate stellate block is also imperative in those not uncommon cases of sudden perceptive loss of hearing in one or both ears, usually in young healthy adults Injection must be very early in these cases, or the cochlear damage becomes irreversible, if, however one is fortunate in seeing the patient soon enough quite remarkable rises in hearing level can be obtained by this means Sudden deafness, especially of perceptive type, should therefore be considered an emergency and treated accordingly

Omagh,
co Tyrone

T J WILMOT

SIR,—Your valuable leading article includes the statement "psychological disturbances are common and this is not surprising in patients who are ever expecting further attacks of disabling giddiness"

I entirely agree with this statement and should like to underline it In my experience cases of Ménière's disease are not infrequently referred to the psychiatrist in the first instance in the mistaken belief that the symptoms are wholly psychogenic This is especially likely to happen if the deafness and tinnitus are less severe than the vertigo In these cases the patient's principal complaint may be that he is frightened to go out alone in case he falls over, and this may be thought to be a phobic manifestation in an anxiety state

It is clear that to most people a severe attack of vertigo is a frightening thing and that the fear of subsequent attacks gives rise to a considerable sense of insecurity It is, however, most important to be sure whether or not true vertigo is present, for the treatment of Ménière's disease is quite different from that of agoraphobia

London, W 1

ANTHONY STORR

DANGEROUS CONTAMINANTS IN STORED BLOOD

SIR,—Dr Discombe (Feb 2) concludes *Experientia docebit*, yet he states "Dr Marsh's (Jan 12) criteria for deciding whether death was due to bacterial contamination are not valid" Surely, experience should have taught him better! Even better—perhaps—if he had read what Dr Marsh actually wrote

Deaths due solely to transfusion (Dr Discombe writes) can be classified into (*a*) hæmolytic reactions due to serological incompatibility, stale blood, or blood damaged by heating or freezing, (*b*) bacterial contamination, (*c*) cause unknown So called "pyrogens" are not (usually) living bacteria, and often are the products of bacterial autolysis The acid citrate anticoagulant mixture, which is placed in the collecting bottle before the entry of donor blood, may contain "pyrogens" because the powders used to make up the anticoagulant mixture were accidentally exposed before the solutions were made up Stored distilled water may also be suspect After the solutions have been autoclaved, they may yet be infected by air drawn through a loose bung as the bottle and solution are cooling The process of autoclaving, although deadly for all phases of bacterial life, does not destroy "pyrogens" The transfusion reactions due to "pyrogens" are often of an allergic nature and can be abolished by the administration of anti-histamine drugs Like Irving Babbitt, Dr Discombe may have struck down too much for discrimination, and ignored too much for judgment

A NEW CLINICAL ENTITY?

SIR,—The letter of Professor Nihoul and Dr Quersin-Thiry in your last issue was of great interest to me From some of the 100 cases in this hospital which I have recently surveyed [1] a virus akin to ECHO-9 has been isolated [2] Other cases of aseptic meningitis in the U S.A, from which ECHO-6 virus was isolated, have recently been described [3]

One of the patients whom I studied developed aseptic meningitis five days after his return from holidays in the Netherlands

Leicester Isolation Hospital and Chest Unit CHAVA E ROTEM

UNMARRIED PARENTHOOD

SIR,—Dr Comfort (Jan 26) makes a very good point, which, as he says, is wilfully ignored by responsible bodies from Parliament downwards

In my maternity unit, just over 100 illegitimate babies are born every year Some years ago I questioned every unmarried mother as to whether contraception was practised History of exposure-rate being notoriously inaccurate, I classified them on vaginal examination as habituated to coitus or not, and also made an arbitrary attempt to assess their intelligence A sample of married women (including only 4 primigravidæ) admitting to unwanted pregnancies showed slightly better education The results were as follows

Marital status	*No of women*	*Intelligent*	*Habituated to coitus*	*Contraception*				
				Condom	*Pessary*	*Diaphragm*	*Combined*	*Nil*
Unmarried	121	87	103	6	10			105
Married	48	34		2	13	2	4	27

As far as I can ascertain, so called sex education seems to be limited to the processes associated with pregnancy and delivery, while the equally natural but often socially less desirable processes leading up to conception are left in an idyllic cloud

Prevention is said to be better than cure, and certainly it is better than abandoning the victim to her fate

London W 1 GILBERT DALLEY

SIR,—Dr Comfort's plea for dissemination of contraceptive knowledge as a first step in preventing unwanted pregnancies deserves support

The social attitudes to the problem of unmarried motherhood vary widely from one individual to another, but the general community attitude is ostrich like because we fail to recognise that, in spite of moral teachings and social pressure sexual union will occur and because we fail to prevent the consequences of coition by active steps to teach the use, and to ease the supply, of contraceptive materials Hence the miseries of unwanted pregnancies and children

As 20% of the first children born in 1953 were conceived out of wedlock (i e 8 months or less after marriage) the problem cannot be said to be small Mr Greenland also shows (Jan 19) that among mothers aged 16–19 65–69% of first children are conceived out of wedlock This would suggest that the logical place to teach the rudiments of contraception is in the schools

Fawley, Hampshire A WARD GARDNER

THE FUTURE OF NURSING

SIR,—I cannot this time complain that the response to my letter (Jan 5) has been disappointing! It may be that one could have wished for more discussion of the subject by doctors, but at least the subject is live —indeed lively

Your own leading article (Jan 26) contains, as one would expect, a great deal of wisdom Nevertheless, although your opening paragraph stresses the need for a resolution of the differences if hospitals are to continue giving of their best, one is a little frightened that some may regard your wisdom as in line with the paternal pat on the back which endeavours to reconcile a quarrelsome pair of children My purpose in writing is to draw attention to what has been made abundantly plain by at least one of the letters—namely, that there are some members of the nursing profession who seem almost to have reached the "point of no return" in regard to discussion of this subject with doctors Such nurses see people like Dr Ritchie Russell and myself as reactionary types who are standing in the way of a fuller development of the nursing service Our sole purpose I am sure is to voice alarm at the danger of making still more elaborate arrangements for the higher training of nurses when the existing structure at the lower level is faulty

May I suggest that one of our dangers in discussing the subject is the present-day fashion for loose analogies and the formation of fine sounding phrases which may mean little? For example, it is common to speak of the nurse's place in the "health team" The word "team" here is a little dangerous, for most teams are made up of persons of completely equal status Now although I am the first to agree with the importance of bringing the trained nurse fully into discussions—and indeed I welcome and often accept her suggestions—the fact needs to be emphasised that under few circumstances is the trained nurse in Great Britain permitted to make decisions of herself regarding the patient's treatment There are, of course, many areas in the world where the absence of a sufficiency of doctors means that highly trained and dedicated nurses accept a much greater measure of responsibility But, although I would hope that Britain will still produce some of these, I do not consider that training should be focused primarily to that end I suggest that the "team" analogy has a nice "matey" sound but may mean very little

I observe, too, from a leading article in the *Nursing Times* (Jan 11) that the degree course in nursing "would be one way of bringing into the profession those with trained minds and a broad outlook and making the nurse's preparation more attractive to those who now find it intellectually unsatisfying" Does nursing sick people bring intellectual satisfaction? I would doubt it very much Surely such people should be advised to get out of nursing and adopt some other form of service This and such a phrase as caring for "the patient as a whole person" are examples of high falutin' phraseology which make me feel that we have passed very far away from the patient's bedside

British nursing has always taken a very proper pride in its emphasis on bedside nursing Some of us believe that before taking steps to build a superstructure for those who find bedside nursing intellectually unsatisfying there is a need to ensure that there is some thought expended upon the needs of hospital patients and sick people generally In my own view this will involve an appreciation that the present emphasis on "science" should give way to a greater emphasis on "nursing" left-to-right anastomosis We have been unable to find figures of other observers on this point

Finally, two or three days in a general surgical ward is, so far as I can see, no prophylactic against some of the worst sequelæ of head injuries—headaches, dizziness, inability to concentrate, depression, and all the other manifestations of the post concussional syndrome

May I repeat, Sir, that we would welcome help ?

Sunderland T G LOWDEN

RAISED C S F -SUGAR LEVELS

SIR,—With reference to Dr Brafield's question last week, I have noted this occurrence about a dozen times in the past six years Some of the cases have been of poliomyelitis, others of lymphocytic meningitis of undetermined ætiology and others of encephalitis The sugar levels have mostly been about 140 mg per 100 ml, but I can remember two in which it was 180 mg per 100 ml In all these the blood sugar was normal This finding is described by Purves Stewart[1] as occurring in epidemic encephalitis (Incidentally he does state that it forms a diagnostic point in contrast with poliomyelitis, which in the light of Dr Brafield's and my experiences is incorrect) The older neurologists did not, however, have the facilities for virus examinations that we have today Dementia præcox and cerebellar abscess are also cited as causes

The mechanism is, I believe, irritation of the medullary sympathetic centre

It is also stated that diabetes mellitus is not likely to be confused with encephalitis That this is untrue is illustrated by the tragic case of an 8 year-old boy admitted to a fever hospital with vomiting, drowsiness, and abdominal pain Acute gastritis or encephalitis were suspected The C S F sugar was 800 mg per 100 ml shortly before death The blood-sugar could not be estimated, but I think there is no doubt that he was in diabetic coma

Hull J G ALEXANDER

NEONATAL COLD INJURY

SIR,—Last week's paper by Dr Mann and Dr Elliott is of great importance to all those concerned with the care of infants It may be of interest to recount briefly our experience in Bristol, as it differs in some respects from that of Dr Mann

We have records of 13 instances of cold injury with 3 deaths from 1953 to 1956 An analysis of these cases shows

Sex distribution males, 12, females, 1 Delivery home, 11, hospital, 2 (symptoms developing several days after discharge) Age on admission less than 24 hours, 1, 1–7 days, 7, 8–21 days, 5 Lowest temperature 82–85°F, 3, 86–90°F, 4, very cold but temperature unrecorded, 6 Pre existing conditions cerebral birth injury, 2, immaturity 5, infection, 4 blue asphyxia at birth with development of symptoms within 24 hours, 1, ? hiatus hernia, 1

The clinical features of the disease followed the description of Dr Mann and Dr Elliott, and we agree entirely with their views on management We noted especially that rhinorrhœa and nasal obstruction together with adventitious sounds in the chest often developed after rewarming and did not necessarily indicate infection Apnœic attacks and convulsions also tended to occur after rewarming

The male preponderance in our series is intriguing, and it would be of interest to know if this is general We have not seen cold injury occur in a healthy, full term infant, and in this we are at variance with Dr Mann and Dr Elliott Of our 3 fatal cases, 2 had post-mortem evidence of cerebral birth-injury, 1 with a tentorial tear, the other with generalised cerebral œdema, pulmonary hæmorrhage, and patchy atelectasis, following a prolonged labour and forceps delivery The 3rd infant showed immaturity and necropsy evidence of generalised asphyxial hæmorrhages, with pulmonary hyaline membrane and resorption atelectasis

Of the non-fatal cases, on admission 4 had infections which we feel preceded the hypothermia 3 infants had purulent rhinitis, in 2 cases due to a penicillin-sensitive, coagulase positive *Staphylococcus aureus*, and 1 due to pneumococcal infection The 3rd had bilateral purulent conjunctivitis, purulent rhinitis, umbilical sepsis, and consolidation of the right middle lobe

In addition to the preventive measures suggested by Dr Mann and Dr Elliott, we would like to stress the greatly increased importance of adequate warmth in those infants whose natural vitality is lowered by any degree of immaturity, trauma, or infection

Department of Child Health,
University of Bristol

THOMAS E OPPÉ
KENNETH SIMPSON

TREATMENT OF SORE THROAT

SIR,—What has become Fry *versus* Wheatley in the treatment of sore throats (Jan 19 and 26) resolves, for those of us who can neither rise to the challenge of a nomogram nor sacrifice our patients' bottoms to our high principles, into the search for a happy medium Something between Dr Wheatley's intractable prophylactic enthusiasm and Dr Fry's fashionable eschewal of oral penicillin is the goal for the likes of us

Just to judge each case, giving the benefit of the doubt in favour of antibiotics, unbedevilled by rigid theories or authoritarian attitudes, is lovely for patient and doctor In any case there are perhaps at least three sorts of tonsillitis which do different things

1 With big red shiny tonsils with or without pyrexia This sort hangs about in children and worries the mother conditioned by welfare clinics It subsides in about 24 hours with penicillin, usually orally but sometimes intramuscularly This type in adults does just as well on aspirin gargle

2 With big red dull tonsils exuding pus This does well with penicillin, oral in children, intramuscular in adults

3 With small very angry looking red tonsils, and a wide spread, rather granular, intensely red pharyngitis, very painful, only seen in adults Penicillin does not seem to touch it When it does not settle on simple measures, it needs four days of tetracycline

Some of the fun of general practice is in using one's own quirks, based on one's own unsystematic, constantly changing, cumulative impressions (is that what's called experience ?), not in obeying others' theoretical or moral mandates

And, whilst, unprotesting, we eat pigs fed on penicillin and include penicillin in poliomyelitis vaccine, where is the logic in railing against the possibility of its inducing resistant strains in inadequate doses ?

London, S W 7 BENJAMIN LEE

SIR,—Like Dr Brumfitt and Dr Slater (Jan 5) subsequent correspondents sensibly discourage the indiscriminate use of antibiotics But the danger of uncontrolled infection by hæmolytic streptococci of group A (especially of type 12) and by diphtheria bacilli, though much diminished in this country, is real, and such other infections as thrush and Vincent's angina are best curtailed by specific treatment

" Sore throat " is not a diagnosis and, for that reason in all severe cases the throat should be swabbed before treatment This preliminary swabbing should be regarded as a rule where there is visible exudate, adenitis, or fever of 100°F or more The laboratory report will often,

---

[1] Purves Stewart, J The Diagnosis of Nervous Diseases London 1945 p 730

I end this letter as I did my last Is this not a subject which demands some kind of formal inquiry? If another *Lancet* Commission is not the answer, is it inappropriate to suggest that the matter is important enough to require consideration at Ministry level?

Department of Infectious Diseases,
University of Glasgow

THOMAS ANDERSON

SIR,—This correspondence has brought to light the great shortage of trained nurses in the hospital service, but no concrete suggestions have so far been made to remedy the position

Undoubtedly the initial trouble is economic

With an ageing population, many nurses today have family commitments which in the days when staff nurses earned £50–60 per annum were unheard of, many old people on small pensions now must have financial help from their children

Male nurses are much in the picture again, and obviously family obligations must be considered sensibly A man cannot support a wife and family, at present living costs, on a staff nurse's salary which at minimum is £425 per annum, taking seven years to reach a maximum of £530 per annum and from which deductions are made for National Insurance, superannuation, meals on duty, uniform, and laundry

Duty covering twenty four hours a day and seven days a week must entail work at all hours, and, while undoubtedly all hospitals would if possible adopt straight shift duties, at present staffing levels this is seldom possible so hospitals have the eternal problem of split duties With families to consider, staff are more and more reluctant to take night and weekend duties, and with no monetary incentive these periods become increasingly difficult to cover

With so many vacancies in hospitals, obvious from the many pages of advertisements in the nursing journals, staff nurses are seldom content to remain in that grade, and very quickly on completion of training take positions at higher salary levels

Today, postgraduate courses are multiplying rapidly, not only in specialist hospitals but in training schools At one time added certificates were useful in obtaining promotion and, to a limited extent, they still are, but no matter how many postgraduate certificates a nurse holds, except in a very few types of work there is no extra salary on completion of the course, or in subsequent employment.

The next factor is the changing function of nursing

A leader in the *Nursing Times* of Jan 11 states that there is a much wider definition than is given in the Nurses' Act, which says "a nurse means a nurse for the sick and nursing shall be construed accordingly" I agree that nurses must share in membership of the health team, but it does seem that the hot house nurturing of the healthy against something which may not happen has been grossly overdone, to the detriment of care of the sick, and, because most preventive health organisations can be conducted on Mondays to Fridays between 9 A M and 5 P M, of course large numbers take such posts In these days of well guarded machinery is it really necessary to have such an exodus of trained nurses from the hospitals to the factories, and are these nurses really more competent in dealing with accidents than the well trained first aid team?

Then back to the question of nurse training

The large majority of men and women taking up this work enter their training with a clear cut picture of nursing the sick, and in the past that ambition was fostered and encouraged, with the ultimate result of well trained nurses prepared to do every duty in the care and comfort of their patients Now it would seem that nurse training is educating the nurse beyond that level to an unhappy state wherein she is neither nurse nor doctor, and wherein, on completion of training, it is no longer her duty to do the intimate treatments like bathing, feeding, bed panning, care of pressure points, and making beds—all things which to a sick person mean far more than non touch technique, and during which duties a nurse really gets to know her patient's anxieties, fears, symptoms, and needs These duties are now passed on to the assistant nurse or to the completely untrained nursing auxiliary

It is no wonder that many medical men are now saying that the assistant nurse should be made the nurse and the S R N be called something else

Of course there are far too few assistant nurses—the further dilution of the profession in 1955 has militated against recruitment Can any sensible person really think it is worth while to take a secondary grade of nurse training, when the completely untrained can earn practically the same salary and do much the same work, and when on completion of training the assistant nurse is limited in what she can do except under supervision—the classic example being hypodermic injections—and cannot hope ever to gain promotion?

A new approach is needed—a basic training for nurses at a three-year minimum, the potential S R N and S E A N not segregated from each other but working together with exactly the same practical training. Those who do not wish to do theoretical examinations should be examined in practical subjects only, entitling them to the hospital certificate of practical efficiency, which in turn should permit them to be entered on a register known possibly as the "Qualified Nurses' Register," and those wishing to take the whole State examination still being classified as State-registered nurse

I would like to see some organisation like the British Nurses' Association upholding a sane and balanced view of what nursing really means This association, formed in 1887, included liberal-minded leaders of the medical and nursing professions, and could be the agency whereby the nursing profession would once more get its feet firmly planted on the ground

G G GOODCHILD
Matron

A RAPID BLOOD-SUGAR SCREENING METHOD

SIR,—We were interested to read the letter by Dr Kohn (Jan 26) We have found that satisfactory results can be obtained with plasma or serum from capillary blood—about 0 5 ml of blood can easily be collected from an ear or finger prick into a small tube, and after about 20 minutes enough plasma or serum will separate to do the test by dipping the tape

A 'Tes Tape' reading of "0" always means a blood sugar of less than about 60 mg per 100 ml It is usually possible to equate a tes-tape reading of "+" with a blood sugar of 60–150 mg, of "++" with a blood sugar of 150–250 mg, of "+++" with a blood sugar of 250–400 mg leading to "++++" with a blood sugar above 500 mg Absolutely reliable readings were obtained at either end of the scale

We should like to thank Messrs Eli Lilly for supplying 'Tes Tape'

HEAD INJURIES

SIR,—Mr Alexander (Jan 26) advises me to consult my neurosurgeon by telephone in difficult cases of head injury, and implies that in such cases a neurosurgeon at the end of a wire is wiser than I am by the side of my patient I do so consult my neurosurgeon, and I willingly confess that the implication is correct But should this be so? My neurosurgeon happens to be one who has thought deeply and given some advice on this problem[1] I myself[2] have made an attempt to define conditions upon which transfer should be considered But I am by no means satisfied with my own attempts, and I am sure my neurosurgeon will agree that there is still much to be done before we can be satisfied—even with his!

We have long observed the criterion Mr Alexander advises for local admissions—that anyone with a history of unconsciousness, however transitory, should be admitted Nevertheless on the one hand this does not gather in all the cases needing surgical care—as the

inquest reports you quote illustrate only too well—and on the other hand it gathers in nearly three times as many as do need it This wastes their time as well as ours, and this is often forgotten

[2] Lowdon, T G The Casualty Department. Edinburgh 1955 p 227

Finally, two or three days in a general surgical ward is, so far as I can see, no prophylactic against some of the worst sequelæ of head injuries—headaches, dizziness, inability to concentrate, depression, and all the other manifestations of the post-concussional syndrome

May I repeat, Sir, that we would welcome help ?

Sunderland T G LOWDEN

RAISED C S F -SUGAR LEVELS

SIR,—With reference to Dr Brafield's question last week, I have noted this occurrence about a dozen times in the past six years Some of the cases have been of poliomyelitis, others of lymphocytic meningitis of undetermined ætiology and others of encephalitis The sugar levels have mostly been about 140 mg per 100 ml, but I can remember two in which it was 180 mg per 100 ml In all these the blood-sugar was normal This finding is described by Purves Stewart [1] as occurring in epidemic encephalitis (Incidentally he does state that it forms a diagnostic point in contrast with poliomyelitis, which in the light of Dr Brafield's and my experiences is incorrect) The older neurologists did not, however, have the facilities for virus examinations that we have today Dementia præcox and cerebellar abscess are also cited as causes

The mechanism is, I believe, irritation of the medullary sympathetic centre

It is also stated that diabetes mellitus is not likely to be confused with encephalitis That this is untrue is illustrated by the tragic case of an 8 year-old boy admitted to a fever hospital with vomiting, drowsiness, and abdominal pain Acute gastritis or encephalitis were suspected The C S F sugar was 800 mg per 100 ml shortly before death The blood sugar could not be estimated, but I think there is no doubt that he was in diabetic coma

Hull J G ALEXANDER

NEONATAL COLD INJURY

SIR,—Last week's paper by Dr Mann and Dr Elliott is of great importance to all those concerned with the care of infants It may be of interest to recount briefly our experience in Bristol, as it differs in some respects from that of Dr Mann

We have records of 13 instances of cold injury with 3 deaths from 1953 to 1956 An analysis of these cases shows

Sex distribution males, 12, females, 1 Delivery home, 11, hospital, 2 (symptoms developing several days after discharge) Age on admission less than 24 hours, 1, 1–7 days, 7, 8–21 days, 5 Lowest temperature 82–85°F, 3, 86–90°F, 4, very cold but temperature unrecorded, 6 Pre existing conditions cerebral birth injury, 2, immaturity, 5, infection, 4 blue asphyxia at birth with development of symptoms within 24 hours, 1, ? hiatus hernia, 1

The clinical features of the disease followed the description of Dr Mann and Dr Elliott, and we agree entirely with their views on management We noted especially that rhinorrhœa and nasal obstruction together with adventitious sounds in the chest often developed after rewarming and did not necessarily indicate infection Apnœic attacks and convulsions also tended to occur after rewarming

The male preponderance in our series is intriguing and it would be of interest to know if this is general We have not seen cold injury occur in a healthy, full term infant, and in this we are at variance with Dr Mann and Dr Elliott Of our 3 fatal cases, 2 had post-mortem evidence of cerebral birth-injury, 1 with a tentorial tear, the other with generalised cerebral œdema, pulmonary hæmorrhage, and patchy atelectasis, following a prolonged labour and forceps delivery The 3rd infant showed immaturity and necropsy evidence of generalised asphyxial hæmorrhages, with pulmonary hyaline membrane and resorption atelectasis

Of the non-fatal cases, on admission 4 had infections which we feel preceded the hypothermia 3 infants had purulent rhinitis, in 2 cases due to a penicillin sensitive, coagulase positive *Staphylococcus aureus*, and 1 due to pneumococcal infection The 3rd had bilateral purulent conjunctivitis, purulent rhinitis, umbilical sepsis, and consolidation of the right middle lobe

In addition to the preventive measures suggested by Dr Mann and Dr Elliott, we would like to stress the greatly increased importance of adequate warmth in those infants whose natural vitality is lowered by any degree of immaturity, trauma, or infection

TREATMENT OF SORE THROAT

SIR,—What has become Fry *versus* Wheatley in the treatment of sore throats (Jan 19 and 26) resolves, for those of us who can neither rise to the challenge of a nomogram nor sacrifice our patients' bottoms to our high principles, into the search for a happy medium Something between Dr Wheatley's intractable prophylactic enthusiasm and Dr Fry's fashionable eschewal of oral penicillin is the goal for the likes of us

Just to judge each case, giving the benefit of the doubt in favour of antibiotics, unbedevilled by rigid theories or authoritarian attitudes, is lovely for patient and doctor In any case there are perhaps at least three sorts of tonsillitis which do different things

1 With big red shiny tonsils with or without pyrexia This sort hangs about in children and worries the mother conditioned by welfare clinics It subsides in about 24 hours with penicillin, usually orally but sometimes intramuscularly This type in adults does just as well on aspirin gargle

2 With big red dull tonsils exuding pus This does well with penicillin, oral in children, intramuscular in adults

3 With small very angry looking red tonsils, and a wide spread, rather granular, intensely red pharyngitis, very painful, only seen in adults Penicillin does not seem to touch it When it does not settle on simple measures, it needs four days of tetracycline

Some of the fun of general practice is in using one's own quirks, based on one's own unsystematic, constantly changing, cumulative impressions (is that what's called experience ?), not in obeying others' theoretical or moral mandates

And, whilst, unprotesting, we eat pigs fed on penicillin and include penicillin in poliomyelitis vaccine, where is the logic in ruling against the possibility of its inducing resistant strains in inadequate doses ?

London, S W 7 BENJAMIN LEE

SIR,—Like Dr Brumfitt and Dr Slater (Jan 5) subsequent correspondents sensibly discourage the indiscriminate use of antibiotics But the danger of uncontrolled infection by hæmolytic streptococci of group A (especially of type 12) and by diphtheria bacilli, though much diminished in this country, is real, and such other infections as thrush and Vincent's angina are best curtailed by specific treatment

" Sore throat " is not a diagnosis and, for that reason, in all severe cases the throat should be swabbed before treatment This preliminary swabbing should be regarded as a rule where there is visible exudate, adenitis, or fever of 100°F or more The laboratory report will often,

---

[1] Purves Stewart J The Diagnosis of Nervous Diseases London 1945 p 730

I end this letter as I did my last Is this not a subject which demands some kind of formal inquiry? If another *Lancet* Commission is not the answer, is it inappropriate to suggest that the matter is important enough to require consideration at Ministry level?

Department of Infectious Diseases,
University of Glasgow — **Thomas Anderson**

SIR,—This correspondence has brought to light the great shortage of trained nurses in the hospital service, but no concrete suggestions have so far been made to remedy the position

Undoubtedly the initial trouble is economic

With an ageing population, many nurses today have family commitments which in the days when staff nurses earned £50–60 per annum were unheard of, many old people on small pensions now must have financial help from their children

Male nurses are much in the picture again, and obviously family obligations must be considered sensibly A man cannot support a wife and family, at present living costs, on a staff nurse's salary which at minimum is £425 per annum, taking seven years to reach a maximum of £530 per annum and from which deductions are made for National Insurance, superannuation, meals on duty, uniform, and laundry

Duty covering twenty four hours a day and seven days a week must entail work at all hours, and, while undoubtedly all hospitals would if possible adopt straight shift duties, at present staffing levels this is seldom possible so hospitals have the eternal problem of split duties With families to consider, staff are more and more reluctant to take night and weekend duties, and with no monetary incentive these periods become increasingly difficult to cover

With so many vacancies in hospitals, obvious from the many pages of advertisements in the nursing journals, staff nurses are seldom content to remain in that grade, and very quickly on completion of training take positions at higher salary levels

Today, postgraduate courses are multiplying rapidly, not only in specialist hospitals but in training schools At one time added certificates were useful in obtaining promotion and, to a limited extent, they still are, but no matter how many postgraduate certificates a nurse holds, except in a very few types of work there is no extra salary on completion of the course, or in subsequent employment.

The next factor is the changing function of nursing

A leader in the *Nursing Times* of Jan 11 states that there is a much wider definition than is given in the Nurses' Act, which says "a nurse means a nurse for the sick and nursing shall be construed accordingly" I agree that nurses must share in membership of the health team, but it does seem that the hot house nurturing of the healthy against something which may not happen has been grossly overdone, to the detriment of care of the sick, and, because most preventive health organisations can be conducted on Mondays to Fridays between 9 A M and 5 P M, of course large numbers take such posts In these days of well guarded machinery is it really necessary to have such an exodus of trained nurses from the hospitals to the factories, and are these nurses really more competent in dealing with accidents than the well trained first aid team?

Then back to the question of nurse training

The large majority of men and women taking up this work enter their training with a clear cut picture of nursing the sick, and in the past that ambition was fostered and encouraged, with the ultimate result of well trained nurses prepared to do every duty in the care and comfort of their patients Now it would seem that nurse training is educating the nurse beyond that level to an unhappy state wherein she is neither nurse nor doctor, and wherein, on completion of training it is no longer her duty to do the intimate treatments like bathing, feeding bed panning, care of pressure points, and making beds—all things which to a sick person mean far more than non touch technique, and during which duties a nurse really gets to know her patient's anxieties, fears, symptoms, and needs These duties are now passed on to the assistant nurse or to the completely untrained nursing auxiliary

It is no wonder that many medical men are now saying that the assistant nurse should be made the nurse and the S R N be called something else

Of course there are far too few assistant nurses—the further dilution of the profession in 1955 has militated against recruitment Can any sensible person really think it is worth while to take a secondary grade of nurse training, when the completely untrained can earn practically *the same salary and do much* the same work, and when on completion of training the assistant nurse is limited in what she can do except under supervision—the classic example being hypodermic injections—and cannot hope ever to gain promotion?

A new approach is needed—a basic training for nurses at a three year minimum, the potential S R N and S E A N not segregated from each other but working together with exactly the same practical training Those who do not wish to do theoretical examinations should be examined in practical subjects only, entitling them to the hospital certificate of practical efficiency, which in turn should permit them to be entered on a register known possibly as the "Qualified Nurses' Register," and those wishing to take the whole State examination still being classified as State-registered nurse

I would like to see some organisation like the British Nurses' *Association upholding a sane and balanced view* of what nursing really means This association, formed in 1887, included liberal minded leaders of the medical and nursing professions, and could be the agency whereby the nursing profession would once more get its feet firmly planted on the ground

Parliament

QUESTION TIME

Group Practices

Dr BARNETT STROSS asked the Minister of Health how many group practices now existed, whether he was satisfied that sufficient *loan capital was still* available for them, and what amount of increase over the annual sum of £100,000 was contemplated —Mr DENNIS VOSPER replied The total number is not known, but loans to about 100 such practices have been approved in England and Wales and the money involved is about £450,000, the fund is now increasing by over £100,000 a year and I think this should be sufficient

Health Centres

Mr W J PROCTOR asked the Minister what areas were now provided with a health centre under the National Health Service, and what proposals he had for extending the health centres provisions of the National Health Service Act —Mr J K VAUGHAN-MORGAN, parliamentary secretary to the Ministry *of* Health, replied The *following centres* have been provided

Berkshire County Council	Faringdon Health Centre
Bristol County Borough	William Budd Health Centre
London County Council	Woodberry *Down* Health Centre
Nottingham County Borough	John Ryle Health Centre
Essex County *Council*	*Harold Hill*
Gloucestershire County Council	Hesters Way Estate
Sunderland County Borough	Alderman Jack Cohen Health Centre

In addition, premises were taken over in July, 1948, by 6 *local authorities* so that general *medical or dental services could be continued there Current restrictions on capital* expenditure rule out further provision for the time being

Dr STROSS asked the Minister how many *local* authorities had applied during 1956 for permission to build health centres, the average estimated cost, and how many medical-practitioner suites were to be made available —Mr VAUGHAN MORGAN replied 4 authorities applied for approval for schemes where building was ready *to* start The average estimated building cost was £25,000 and a total of *15* medical practitioner suites was included In the case of 4 other authorities, approval in principle was sought or consideration of proposals was continued during the year Dr STROSS Would the Minister agree that it is important to press forward with all types of health centres so that we *may* find out which are best ? Will he accept that £25,000 seems a much more reasonable figure than the fantastic sum spent on Woodberry Down, which I hope we shall never see repeated ?—Mr VAUGHAN MORGAN I am sure that the Minister would be in agreement with the imputation in the last part of the question We should do well to remember the approach of the Guillebaud Committee in this matter It was in favour of pursuing an *experimental approach towards development*

Cancer Research

Mr R R HARRIS asked the Minister, as representing the Lord President of the Council, what information his department *now had on the connection* between diesel engine fumes and the increase in cancer —Mr VOSPER The investigations being made under the auspices of the Medical Research Council into the nature and effects of the exhaust products of diesel engines have provided no evidence to support the suggestion *that these fumes are a cause of cancer*

Mr G D N NABARRO Is it not a fact that diesel oil fumes in congested urban areas are a direct contributory factor to smog ? As smog has detrimental effects upon everybody's lungs, is it not reasonable to suppose that diesel *oil fumes have an important* bearing upon the incidence of lung cancer ?—Mr VOSPER I dare say that that is so Investigations are continuing But the direct association between diesel fumes and cancer has not been proved

Mr MARCUS LIPTON asked the Minister how much was being spent from public funds on research into the connection between smoking and lung cancer —Mr VOSPER In the current financial year the Medical Research Council is spending about £29,000 on research on this subject Most of this sum comes from the lung cancer research fund put at the disposal of the council by a group of British tobacco manufacturers Mr LIPTON Is it *not quite deplorable that the Government* are making no contribution at all towards research in this matter ? Is the fact that the Government are making no contribution to be explained by the policy announced by the Chancellor of the Exchequer recently that the Treasury does *not* want *too many* people to stop smoking ? Is that not an immoral and infamous attitude ?—Mr VOSPER It is not of course, true that the Government are *making no contribution* They are making *some contribution towards* this particular piece of research, and the Medical Research Council this year spent £327,000 from public funds on cancer research as a whole, but the mere expenditure of money will not necessarily provide the answer *to this problem* Mr *LIPTON In view of* the proved connection between smoking and lung cancer, has the Minister any comment to make *on* what apparently is the policy of the Treasury, that the Treasury does not want too many people to stop smoking ?—Mr VOSPER I am anxious *to* find the solution *to* this problem, and I would not be influenced by any views of the hon Member

A Pep Drug

Mr MAURICE EDELMAN asked the Minister whether he had studied the claims contained in the advertisement of a proprietary drug, particulars of which had been sent to him, what was its composition, whether it was to be included in *Prescriber's Notes*, what equivalent preparation of a non proprietary nature was already included in *Prescriber's Notes*, and at what cost —Mr VOSPER 50 milligrammes of caffeine per tablet The preparation has been noted for inclusion in the list of preparations advertised to the public which doctors have been asked not to prescribe A standard drug of similar therapeutic effect is included in the *British Pharmaceutical Codex*, retail price 11½*d* for 25 tablets, and I am advised that its clinical use is small and diminishing Mr EDELMAN Is the Minister *aware that this so called* pep up *drug is retailing at 2s 6d per* phial ? Is it not undesirable that this drug should be available indiscriminately, even to children, without prescription ? Are there not certain *social*—quite apart from physical—dangers arising from the promiscuous use *of* this drug ?—Mr VOSPER I understand that the drug *is* not harmful and that in fact the the effect of one tablet is about equivalent to that of a cup of tea or coffee I agree that on social grounds it is undesirable, and for that reason it has been included in the list of drugs which should not be prescribed

Jobs for Tuberculous People

Mrs SLATER asked the Minister of Labour what advice or help was given to encourage employment *of* people suffering from tuberculosis —Mr ROBERT CARR, parliamentary secretary to the Ministry of Labour *and National* Service replied My officers do all they can, in coöperation with chest physicians, to help the tuberculous to obtain employment For this purpose, all the services provided under the Disabled Persons (Employment) Act, including industrial rehabilitation and training, are available to the tuberculous *as they* are to other disabled people Special *facilities for* training and employment under sheltered conditions are provided by Remploy, and by some voluntary bodies and local authorities

Mr WILFRED PALING Is the Minister aware that Government departments do not make matters too easy *for people* who have had tuberculosis ? Is he aware that, if a man *applies for any unestablished* post in a department, he has to state specifically whether he has ever suffered from tuberculosis or not, and that, when most applicants read that, they are likely to jump to the conclusion that their case has been damned even before it is considered ?—Mr CARR *I do not* think the *right hon* Gentleman's conclusion is necessarily justified *It probably is right* that employers should get this information We must, of course, while providing opportunities for the tuberculous, protect the health of other people as well

Industrial Health Services

Mr F T WILLEY asked the Minister of Labour when he expected to be able to make a statement on industrial health services and organisation as envisaged in the report on the Staffing and Organisation of the Factory Inspectorate —Mr IAIN MACLEOD replied *I am not able to say* when I shall be in a position to make such a statement I think that it is more *important* that we *got* the right answer than that we come to a conclusion quickly In particular, I am sure *that* we want *the result of the important* survey going on in Stoke-on *Trent into the pottery industry,* which will not be available *until the end of the year*

Mr WILLEY asked the Minister the present strength and grades of the medical inspectorate of his department, and to what extent he was proposing to increase the numbers in any grade during 1957 —Mr MACLEOD replied There are at present on the strength of the medical inspectorate 1 senior medical inspector, 3 deputy senior medical inspectors, and 11 medical inspectors I hope to increase the strength by 3 medical inspectors during 1957, to fill existing vacancies —Mr WILLEY While I appreciate that the increase this year is encouraging, would not the Minister recognise that this service appears to be inadequate, and that that is another reason for our hoping to get a reply earlier than he has indicated in his reply to a previous question ?—Mr MACLEOD This and the previous question are closely linked The reason why, in part at any rate, no suggestions have been made for increases in the cadre is that it was thought that those changes should await the decisions on policy to which I referred in my earlier answer

Mr A M SKEFFINGTON asked the Minister when it was proposed to announce the successor to the senior medical inspector of his department who was to retire this year —Mr MACLEOD The senior medical inspector of factories will retire at the end of August next I hope to be able to announce his successor well before August Mr SKEFFINGTON Does the Minister realise that many people on both sides of industry regard the work of this inspectorate as of great importance, and want to see it extended, as the Minister has indicated in reply to an earlier question Therefore, in building up an effective department, the name of the gentleman who is to be in charge should be known soon Mr. MACLEOD I recognise that, and I attach the greatest importance to the medical inspectorate

Number of Mental Defectives

The number of mental defectives detained in hospitals and colonies in England and Wales has risen from 4411 in 1916 to 60,457 in 1955 The figure for 1955 includes 6336 patients out on licence from these institutions

Use of Trilene

The use of 'Trilene' by domiciliary midwives is on the increase At the end of 1955 about 236 trilene sets were in use in England and Wales, while the number at the end of 1956 had risen to about 900

Hospital Waiting-lists

The number of patients awaiting admission in England and Wales on Dec 31, 1955, was 454,878 This is a reduction of some 20,000 since the end of 1954 and of 71,000 since the end of 1953

Cost of Prescriptions

The average cost per prescription dispensed in November 1956, was 5*s* 1*d* compared with 4*s* 5 81*d* in November, 1955

Obituary

CHARLES LEONARD GIMBLETT

M D Camb , M R C P , F R C S

Mr Gimblett, late senior surgeon to the Westminster branch of Moorfields, Westminster, and Central Eye Hospital, London, died on Jan 21 at the age of 66

The son of Robert Wheddon Gimblett, he was educated at Clifton College and at Gonville and Caius College, Cambridge, and received his clinical training at St Thomas's Hospital After qualifying, in 1914, he held several house-appointments there, including that of house-surgeon in the ophthalmic department where he came under the influence of Fisher and Hudson During the 1914–18 war he served as surgeon lieutenant in the Royal Navy In 1919 he took the M R C P and in 1922 the F R C S Early in his career he decided to specialise in ophthalmology, and he prepared himself with characteristic thoroughness

He was elected to the honorary staffs of the Royal Westminster Ophthalmic Hospital and the Royal Northern Hospital in 1923 During the late war he was ophthalmic surgeon to the Haymeads E M S Hospital, Bishop's Stortford In 1947 he became senior surgeon at the Royal Westminster Ophthalmic Hospital, shortly before it amalgamated with Moorfields and the Central London Ophthalmic Hospitals, and he retired last August

He was fond of children and for many years was consultant to the Lord Mayor Treloar Orthopædic Hospital, and he was chairman of the medical advisory committee till his death His interest in the problems of squint had been stimulated by the teaching of Claud Worth, and Gimblett was instrumental in forming the orthoptic department at the Royal Westminster Ophthalmic Hospital, of which he was given charge He was largely responsible for developing the training school and getting recognition for orthoptists as medical auxiliaries He was the first chairman of the British Orthoptic Board

P McG M writes

Gimblett was essentially a clinical ophthalmologist of the highest order His early training in general medicine and surgery was of immense value to him He was indefatigable in his work, never sparing himself and in spite of two severe illnesses he continued his hospital work for some time after he had reached retiring age In private life he was interested in mediæval art and on holiday he enjoyed sailing and swimming He was beloved by his patients because of his tact and patience and by his colleagues because of his loyalty and friendship

He married in 1935 Andreen daughter of Duncan McNicol She survives him with two sons

HORACE MINTON SHELLEY

M R C P , F R F P S , D T M & H

Dr H M Shelley was director of medical and health services in Cyprus during the later stages of the campaign which rid the island of the malaria mosquito After he retired in 1952 he made his home there, and he died on Jan 26 at the age of 56 while on a voyage to Greece

He qualified from the University of Sheffield in 1923 and joined the Colonial Medical Service the following year From 1924 to 1939 he served in Nyasaland, at first as a medical officer In 1927 he took the D T M & H and in 1934 he was elected F R F P S The same year he was appointed government pathologist He took the M R C P in 1938, and in 1939 he transferred to Tanganyika as senior medical officer In 1947 he became D M S in Cyprus, and he held this post until his retirement

W M A , who visited Cyprus while Shelley was D M S , writes

I carried away with me the impression of a deeply devoted doctor dedicated to the concept of the best possible medical service He strove consistently for the integration of all communities in Cyprus His ideal was a service in which all worked together, not as Englishman, Greek, or Turk, but as Cypriots It was characteristic of his devotion to this cause that he settled in Cyprus after retirement It must have been an especially deep sorrow to him to see how deeply divided have become the peoples he longed to see live and work in amity The hospitality he and Mrs Shelley gave to all visitors was deeply appreciated

Of his work for the Colonial Medical Service E D P writes

Dr Shelley's devotion to duty, enthusiasm, warm humanity, and consideration for others were qualities which endeared him to many He always retained his interest in clinical medicine and after retirement became consulting physician to the Limassol government hospital in Cyprus His name will long be remembered with gratitude in the countries where he served so devotedly and faithfully

JOHN HOWARD SIMMONS

M D Lond , M R C P

Dr J H Simmons, consulting physician to the Lewisham group of hospitals, died on Jan 17, at the age of 54

He qualified from King s College Hospital in 1925, and after holding house-appointments there he spent some time in general practice In 1930 he took the M R C P and the following year the M D , and soon afterwards he joined the London County Council's hospital service as a junior medical officer Before he was appointed as physician specialist to Lewisham Hospital in 1941 he had held the post of deputy medical superintendent at Mile End Hospital and at St Charles' Hospital

Under the National Health Service he became consultant physician, and he served Lewisham Hospital and St John's Hospital as senior physician He was always interested in hospital administration, he was chairman of the Lewisham Hospital staff committee for a time, and later for three years he served as chairman of the group medical advisory committee His tactful handling of many difficult problems proved a valuable asset in the early stages of the development of the Lewisham hospitals as a group

After the retirement of the former medical superintendent in 1951, Dr Simmons undertook the medical administrative duties of the hospital—with the title of executive medical officer—but he still gave the greater part of his time to his clinical work

A colleague writes

Dr Simmons's opinion was respected and widely sought, and his kindly nature and good advice brought him many friends Much of his time was given to the welfare and medical care of the nursing staff, who held him in great affection He was fond of his garden to which he gave many of his leisure hours He shared his happy family life freely with a large circle of friends, and at Christmas it was the custom for him and his wife to entertain Dominion students

Dr Simmons leaves a widow and daughter

ALFRED CHAD TURNER WOODWARD

Kt, M B Edin, F R C S

Sir Chad Woodward, who died in Birmingham on Feb 2, at the age of 76, was educated at Radley and at Edinburgh University, where he graduated M B in 1904 Returning to the West Midlands he served as resident surgeon in the general hospital, Birmingham, taking his F R C S in 1911 For a time he practised in London, but in 1914 he joined the R A M C in which he continued to serve as an active surgeon until 1919 He succeeded his elder brother, who had been killed in the war, as heir of the Arley Castle estates in Worcestershire—an obligation which necessitated his retirement from medicine Instead he became an authority on forestry, and, like his father before him, was mindful of the public responsibilities of a land-owner

In 1926 he was elected to the Worcestershire County Council He served for many years as chairman of the education committee, vice-chairman of the council, and chairman of the standing joint committee From 1939 to 1943 he served on the Radium Commission In 1942 he was elected chairman of the county council and held office until 1955 He was a governor of the London School of Hygiene and Tropical Medicine and of Birmingham University He was knighted in 1944

A colleague writes

Woodward, who was tall and handsome in appearance but somewhat quiet in manner and reserved, was an able administrator and a gifted chairman—sympathetic but impartial, firm yet courteous, and always with that redeeming light touch at the right moment He was a well read man knowledgeable in many fields, yet he always retained an interest in medicine and enjoyed "talking shop" with a member of his former profession

He married in 1934 Martha Grace, daughter of Canon Rowland Wilson She survives him with three daughters

Notes and News

THE PORCUPINE MAN

In a lecture at University College, London, on Jan 31 Prof L S Penrose, F R S, told the story of Edward Lambert, the porcupine man, and his progeny

In the transactions of the Royal Society for 1731, he was described by John Machin as "an uncommon case of distempered skin" Born in Suffolk in 1716, he appeared normal at birth, but, when he was 6 weeks old his skin, except for the palms, became like the bark of a tree, with many spines like those of a hedgehog His parents and siblings were unaffected, and Machin noted that the mother had not been frightened while carrying him

After she died, his father took him to London to be exhibited as a freak His appearance cannot have been utterly repulsive (he was described as well proportioned, with a florid complexion), for in 1744 he married, and begot a son who was similarly affected and who was presented to the public "with other strange animals" Two grandsons (John and Richard) were also affected and toured Continental cities, where they were examined by many eminent scientists and physicians, including Tilesius and Alibert They were said to be intelligent and expert linguists, though their veracity, it seems, could not be entirely relied on John had a son, and apparently the anomaly died with him

It is now thought that these men had familial ichthyosis hystrix, a rare condition which has been seen on both sides of the Atlantic Some of the patients have been women, [illegible] brothers described recently in the United States were similarly affected, and their mother and other relatives had the condition less severely

The genetic interest of the porcupine men lies in the fact that records in the literature seemed to show that all the direct male descendants, and none of the females, were affected It was thought that the disease was a Y borne trait and the putative family tree has appeared often in the literature

But Professor Penrose, and his colleague, Prof C Stern of California, were more critical By examining the parish registers in several Suffolk churches, Penrose disproved some of the imaginative stories of John and Richard (for example, that their grandfather was a scaly American savage brought by sailors from the Davis Strait, and that they had no brothers but seven unaffected sisters) The results of their researches have allowed them to draw a revised pedigree, which shows affected females and unaffected males, and the ichthyosis is now thought to be an autosomal dominant trait They conclude that there is no reliable evidence at present for inheritance by Y-borne genes in man

MIDWIFERY AND DAY-NURSERY COSTS

In his latest report on the civil appropriation accounts[1] Sir Frank Tribe, the auditor general, remarks that the Local Health Statistics for 1954–55 showed that average midwifery costs were £13 3s per maternity case for county boroughs and £16 14s for counties, but the ranges of costs were from £7 7s to £25 6s and from £11 to £58 14s respectively Likewise, the average cost per child in daily attendance at day nurseries was £161 2s per annum for county boroughs and £169 2s for counties, but the ranges of costs were from £86 11s to £424 14s and from £67 16s to £214 14s per annum respectively

CANCER AND PEOPLE

That a carefully planned and conducted educational campaign on the early detection of cancer does not flood doctors' surgeries with hypochrondriacs was shown by Mr John Wakefield, secretary of the Manchester Committee on Cancer, at a conference organised by the Central Council of Health Education on Jan 24 The three other speakers were Mr R W Raven and Dr John Burton, who reviewed the position of cancer and the problems it presented, and Mr Mackenzie editor of the *Sunday Graphic*, who described the results of running a series of articles on cancer, the responses of readers its popularity, and the correspondence evoked

Mr Wakefield told of the programme of instruction introduced into a number of areas, so limited and defined that their experience could be compared with that of their neighbours Large audiences were avoided, in order to encourage informal discussion between the speaker and the group, description

Planning for Safety in the Home

Dr C A Boucher will give a lecture on this subject at 8, Hill Street, London, W 1, on Wednesday, Feb 27, at 3 30 P M The meeting has been arranged by the women's group on public welfare of the Council of Scientific Management in the Home

A New International Society

The Société Médicale Internationale de Photo Cinématographie et Télévision Endoscopiques et de Radiocinématographie was inaugurated, with Professor Soulas as president, on Dec 8 The next meeting will be in Paris on March 9 Dr P H Holinger will act as president, and Prof Chevalier L Jackson as hon secretary at the first annual general meeting, which will be held in New York on June 3 and 4 The permanent hon secretary is Dr J M Dubois de Montreynaud, 4, Rue du General Baratier, Reims, France

Scottish Maternity Services Review

The committee set up by the Scottish Health Services Council to review maternity services in Scotland held their first business meeting on Jan 29 They are hearing oral evidence from selected organisations, and they will be prepared to consider written evidence which may be offered in relation to their terms of reference, which are

> To consider through a professional subcommittee in the first place, the range of provision which should be available in the National Health Service in the interests of the mother and child during pregnancy, confinement, and lying in, and to advise how best such provision can be secured within the framework of the service

The chairman of the committee is Prof G L Montgomery The medical secretary is Dr Mabel Mitchell, and the lay secretary Miss L C Watson, both of the Department of Health for Scotland

Austrian Institute

Prof V Frankl, of the University of Vienna, will give a lecture at this institute, 28, Rutland Gate, London, S W, on Thursday, Feb 21, at 8 30 P M He is to speak on collective neuroses of the present day

Increases for Seriously Disabled War Pensioners

At the beginning of February, some 77,000 seriously disabled war pensioners, most of them veterans of the 1914-18 war, began to draw the improved allowances announced by the Minister of Pensions and National Insurance on Nov 19 (*Lancet*, 1956, ii, 1110)

Exports of Drugs and Medicines

In 1956 British exports of drugs and medicines reached a record of £35,943,000 Of this total, antibiotics accounted for nearly £7 million and vitamins for nearly £3 million. Sulphonamide preparations (£1$^1/_2$ million), aspirin and synthetic antimalarial drugs (£1 million each), and barbiturates, insulin and anti-histamine drugs (£$^1/_2$ million each) also contributed to the total Proprietary medicines not covered by specific headings in the Board of Trade returns amounted to ove £10 million

Australia and India were the leading export markets fo British drugs, with purchases around £3 million Next came Nigeria, Pakistan, South Africa, New Zealand, the Republic of Ireland, and Burma, all taking between £1 million and £2 million Sales to the United States of America increased from £660,000 in 1955 to nearly £1 million last year

---

A new British Standard (B S 2805 1957) specifies a range of straight artery (hæmostatic) forceps of the Spencer Wells pattern having a screw joint and made of stainless steel Provision is made for 5 in, 6 in, 7 in 8 in, and 9 in sizes Copies of this standard (3*s* 6*d*) may be obtained from the sales branch of the British Standards Institution 2, Park Street London, W 1

CHEMICAL CARCINOGENS AND THEIR SIGNIFICANCE*

J W COOK

D Sc, Ph D Lond, F R S, F R I C

VICE CHANCELLOR OF THE UNIVERSITY OF EXETER

THE success achieved by chemotherapy against parasitic organisms gives grounds for hope that chemotherapeutic agents against cancer may eventually be found Hitherto the search has been largely empirical, but, if distinctive differences between normal and malignant tissue were found, the way would be open for a more rational approach Some promising results have recently been reported with modified amino-acids and purines, such as 6-azauracil and 6-mercaptopurine riboside Such substances might be expected to act by displacing some normal components in the synthesis of nucleoproteins

I have been concerned with chemical carcinogens for the past twenty five years, during which time our knowledge of this subject has increased so extensively that I can do no more than touch on some selected aspects

Historical

Sir Ernest Kennaway first showed, in 1930, that cancer could be produced by a pure chemical compound, but this discovery had its origin in observations made by Percivall Pott in the latter part of the eighteenth century Pott described chimney sweep's cancer, which he clearly recognised as an industrial disease and attributed to some peculiar quality of the soot to which the sweeps were exposed This view was vindicated by Passey in 1922, when he showed that skin cancer could be produced in mice by painting them with an ethereal extract of soot The first such experimental production of cancer had been accomplished in 1915 by Yamagiwa, who applied coal tar to the ears of rabbits, and the same agent was shown a few years later by Tsutsui to cause skin tumours in mice This procedure of application to the skin of mice has been used extensively ever since in testing for carcinogenic action

During the 1920s and earlier, other examples of industrial skin cancer became recognised Coal-tar workers were found to be liable to the disease, as also were workers in the Scottish shale oil industry, especially those engaged in handling the paraffin scale A similar liability was found in workers in the Lancashire cotton industry and traced to the action of mineral lubricating oil to which the mule spinners were exposed The question was, therefore, what particular constituents of these materials were responsible for these effects Coal tar, lubricating oil, and shale oil are all complex mixtures, and it became a matter of importance to determine which of their components had these pathological effects The problem was taken up by Kennaway, who tested many of the known constituents of coal tar without result but was able to prepare new forms of carcinogenic tars, the study of which provided valuable clues, especially those arising from the spectroscopic work of Mayneord and Hieger I joined the team at the Cancer Hospital in London in 1929, so that chemical methods could be brought to bear on the problem, and was assisted in these by another young chemist, Hewett

Carcinogenic Hydrocarbons

The efforts of our small team were rapidly crowned with success, and in a relatively short time we had synthesised a considerable range of pure chemical compounds with cancer producing activity, some of them remarkably potent For the most part these were new compounds, prepared for the first time in connection with these studies, and they belong to the class of polycyclic aromatic hydrocarbons The parent compound of the first group of such hydrocarbons found to have this biological action is 1 2-benzanthracene Although in itself it has little or no activity, active compounds arise when substituents are introduced into suitable positions in the molecule By preparing and testing large numbers of compounds we were able to make some rough generalisations about the conditions necessary for carcinogenic activity within this group

Fluorescence spectroscopy of carcinogenic tars provided the clue which led to the discovery of these cancer-producing hydrocarbons They have a fluorescence spectrum similar to that characteristic of the tars The same clue was used by Hieger in the systematic fractionation of coal-tar pitch, which led eventually to the isolation of a very potent carcinogenic hydrocarbon, hitherto unknown, which was shown to be 3 4-benzpyrene This we also synthesised, and the synthetic material was just as active as that isolated from coal tar pitch This hydrocarbon is related in molecular structure to 1 2-benzanthracene It is a fair presumption that 3 4-benzpyrene is responsible, at least in part, for the skin cancer in coal-tar workers Direct proof of this would naturally be difficult to secure

Whether mineral oils have this or similar carcinogenic constituents is still an open question The matter is being investigated under the auspices of the Medical Research Council Chemical separation of pure components of the active fractions of a Kuwait oil is being undertaken by Dr W Carruthers and Mr A G Douglas They have already, in Glasgow, isolated and identified a considerable number of new constituents of the oil, and this work is now being continued in Exeter, in the laboratory of the new M R C Carcinogenic Substances Research Group at the university

The carcinogenic hydrocarbons have very interesting biological properties Applied to the skin of laboratory animals they cause first papillomas and then malignant tumours which have all the usually accepted criteria of carcinomas They show invasion of muscle and they give rise to secondary tumours, usually in the lungs or the axillary glands If the same compounds are applied by subcutaneous injection they cause sarcomas which can be grafted and maintained in successive hosts, apparently indefinitely In fact, with these compounds, cancerous tumours have been obtained in a great variety of tissues and in a number of different species of animal (e g, rats, mice, rabbits, hamsters, guineapigs, and fowls) The tumours also show great variety morphologically, and their nature seems to be determined mainly by the character of the cells in the tissues affected by the carcinogenic agent

Differences between the substances are *quantitative* rather than qualitative Thus, two compounds may vary in the rates at which their application to a given tissue leads to tumour formation, and the relative potencies determined in this way will not necessarily be the same if a different tissue is used as test object To put this last statement in another way, a compound A may give epitheliomas in mice twice as rapidly as a compound B, but in the production of sarcomas in fowls or epitheliomas in rabbits B may prove to give a response three times as rapidly as A

The certainty with which malignant tumours are produced—e g, by painting on mice—with the more potent compounds is very impressive, as also is the smallness of the dose, amounting in the case of the more active compounds to microgramme quantities, with which tumours have been produced If chemical compounds are concerned in the initiation of human cancer in general, as may well be the case, it is important to recognise that we may be dealing with either small amounts of highly active compounds, perhaps acting for a relatively short time, or larger amounts of weakly carcinogenic compounds acting over many years, perhaps the major portion of the normal life span

---

* Abridged from a lecture given to the Devon and Exeter Medico Chirurgical Society on Oct 18, 1956

The intensive research on carcinogenic substances which has been undertaken during the past quarter of a century has complicated rather than simplified the problem Many active compounds are known, not only among the various groups of polycyclic hydrocarbons but also with analogous compounds in which one or more of the aromatic rings has either nitrogen or sulphur as part of its make-up There are also carcinogenic compounds of widely different chemical types in which no *common feature can* be *recognised* These include azo dyes and aromatic amines, both of which groups merit comment

A characteristic of the carcinogenic hydrocarbons is that they act locally, at the site of direct application Injection into the subcutaneous tissue gives spindle-cell sarcomas of connective tissue, application to the skin gives squamous cell epitheliomas, tumours have been obtained by direct application to other tissues—e g, liver, spleen, and brain—and insertion of pellets in the femur and tibia has given osteosarcomas and fibro sarcomas

Azo Dyes

The azo dyes, of which the carcinogenic action was first reported by Yoshida and Kinosita, give, on the other hand, only tumours of the liver (hepatoma and cholangioma), irrespective of the route of administration Metabolic studies support the view that the action of the carcinogenic hydrocarbons is a direct action on the cells, but in the case of the azo dyes the action is probably indirect, resulting from the conversion of the dye in the liver into a carcinogenic metabolic product, which may be an aromatic amine A compound of the latter class, β naphthylamine, has been shown to cause bladder cancer in dogs and is probably responsible for the high incidence of cancer of the bladder found among workers in dyestuffs The evidence incriminating β-naphthylamine in this is so strong that the manufacture of this important dyestuffs intermediate has been abandoned in the United Kingdom

The action of azo dyes in producing liver tumours is also of practical importance inasmuch as compounds of this class have been used for colouring food Dietary deficiency, particularly of protein and riboflavine, seems to be a factor in influencing the production of liver tumours, for which massive doses of the dye are required But the possible carcinogenic effects of these dyes has led a Government committee to recommend that only a restricted list of dyes should be used for colouring food

Other types of compounds which have been shown to be carcinogenic are certain epoxides, such as the diepoxide of vinylcyclohexene, some ethyleneimines, and the so called nitrogen mustards These three groups are all highly reactive chemically, in contrast to the polycyclic hydrocarbons, and they act as cytotoxic agents They appear to act directly on the chromosome mechanism of the cells and, in doing so, bring about effects indistinguishable from those of X rays, which also have a carcinogenic action

In spite of much research we still do not know anything of the mechanism by which the polycyclic hydrocarbons transform normal cells into cancer cells, but it may be associated with the fact that at least *one of them* is known to become firmly attached to skin proteins In a similar way the azo dye butter-yellow has been shown to form a complex with liver proteins, and this is formed more slowly in rats given a protective diet containing added riboflavine These and other findings have suggested that the induction of malignant change is attributable to the gradual deletion of key proteins essential for the control of growth Among the experimental observations which require explanation are the findings that the production of tumour by carcinogenic hydrocarbons can be considerably accelerated by co carcinogens (e g, croton oil) and retarded by other agents (e g, mustard oil)

Tobacco and Lung Cancer

Cancer of the lung has increased at least tenfold during the past thirty years and is well on the way to becoming the most common form of cancer in men Lung cancer has not increased in women to anything like this extent In 1954, for example, in England and Wales, six men died from cancer of the lung for every woman There is now an impressive amount of statistical evidence which seems to incriminate cigarette smoking in the increase of lung cancer, but this is clearly not the only factor In England and Wales in 1950 there were 15,000 deaths attributed to cancer of the lung, and in 1955 the figure had risen to 17,270 A fifth of the victims were non smokers, and in these also cancer of the lung is increasing But the statistical data undoubtedly suggest a much enhanced liability to lung cancer among cigarette-smokers and to a lesser extent among smokers of pipes and cigars

If smoking is the cause of this increase of lung cancer, presumably there are carcinogens in the smoke The tarry condensates of the smoke obtained by smoking cigarettes in machines designed to reproduce the conditions of human smoking have indeed been shown to contain small amounts of polycyclic hydrocarbons, among them 3 4 benzpyrene But the amount is exceedingly small, and there is considerable doubt about whether the concentration is high enough to produce carcinogenic action Wynder, in the United States, has obtained malignant tumours of the skin in mice by the application of tobacco tar prepared in this way, but other workers have obtained purely negative results, and it is possible that, in the preparation of his tar, Wynder had used more drastic conditions, especially as regards temperature of combustion, than we have in normal smoking This question of whether there are harmful amounts of carcinogen in tobacco smoke, and, if so, what is the nature of the carcinogen, is one of the two problems to be investigated in the new carcinogenic substances group of the Medical Research Council in Exeter A major difficulty is that we have not yet a satisfactory method of biological test The lung tumours which have been induced in animals with chemical carcinogens are usually adenomas, and tumours analogous to the bronchocarcinoma of man have not so far been induced experimentally in animals

Atmospheric Pollution

The other main factor which may be concerned in the increase of lung cancer is atmospheric pollution associated with urbanisation and industrialisation Town air is at times heavily contaminated with soot, which is known to contain occluded 3 4-benzpyrene, and this soot is deposited in the lungs of town dwellers Also, experiments have shown that 3 4-benzpyrene may be present in the exhausts of petrol engines and diesel engines under conditions of inefficient running, and there is reason to think that other carcinogens may be present in the fumes from petrol engines

It may well be that a summation effect is operative, *and that the combined* effect of soot, engine fumes, and tobacco smoke will produce sufficient concentration of carcinogen to give lung tumours under conditions where none of these alone would be effective A plausible suggestion is that the solvent action of the constituents of tobacco smoke may extract the benzpyrene absorbed in the soot deposited in the lungs with the result that this carcinogen is brought into intimate contact with the tissues. Kotin of Los Angeles who discussed cancer-morbidity data for different countries and different regions, concluded that the main factors influencing the incidence of lung cancer are environmental and associated with the degree of atmospheric pollution, and that tobacco-smoking plays a subsidiary rôle. Conclusive evidence of the importance, both relative and absolute, of these various factors is going to be very difficult to secure. In the meantime the best advice that can be given, especially to young people, is that it would be well to avoid the large cities, particularly in industrial areas, and to give up smoking.

Cholesterol

I began by recording facts; I have moved into the realm of conjecture; and I am going to finish by becoming frankly speculative. What about cancer of the internal organs of man? Is this due to the action of carcinogenic substances? I can answer this question only in a negative way; there is no evidence to show that it is not. In a malignant tumour induced by a polycyclic hydrocarbon there is no longer present the substance which initiated it, and the fact that such carcinogens cannot be detected in spontaneous tumours is no proof that they were not concerned in the origin of the tumours. Although the known powerful carcinogens have not been detected in tissues or body-fluids, it is suggestive that Hieger and others produced sarcomas in mice by injecting unsaponifiable fractions of the fats extracted from livers not only of patients who had died of cancer but also of non-cancer patients. An invariable constituent of such unsaponifiable fractions is cholesterol, which is notoriously difficult to obtain in a state of complete chemical purity. Tumours have also been induced in a small proportion of the treated mice, with cholesterol samples of various degrees of purity as well as with products formed by oxidation of cholesterol.

Cholesterol and the related bile acids are also of interest from another standpoint. Haslewood and I showed about twenty years ago that the hydrocarbon methylcholanthrene, which may be obtained by relatively simple procedures, involving oxidations, reductions, dehydrations, and dehydrogenations, from some of the bile acids—notably deoxycholic acid—is a very powerful carcinogen. It is a member of the 1 2-benzanthracene group and is closely related to other carcinogens of this group. May it not be that, under some conditions not yet defined, natural steroids present in the body undergo similar chemical transformation into either methylcholanthrene or a related carcinogen? There is no evidence to support this other than a suggestive structural relationship; but it is a possibility which should not be too lightly dismissed.

Sunlight

Then there is skin cancer other than the industrial forms which are known now to be due to the action of chemical carcinogenic agents. I have been surprised to find that this has been stated to be the most common form of cancer in the United States; but it is undoubtedly very prevalent in some parts of the world, especially among people who undergo prolonged exposure to strong sunlight, such as farmers in Australia and South Africa. And there is a precancerous skin condition among seamen that has been called seaman's skin. Excessive exposure to strong sunlight is undoubtedly the primary cause of much of this skin cancer, and skin tumours have been produced experimentally in rats by prolonged exposure to sunlight.

The rays of the sun may have a direction action on the cells; but it is at least possible that the action may be indirect and involve a photochemical conversion of some constituent of the skin into a chemical carcinogen. A substance which suggests itself in this connection is provitamin D, which is known to be converted into the vitamin by ultraviolet light. Provitamin D is closely related to cholesterol and is, in fact, cholesterol from the molecule of which two atoms of hydrogen have been abstracted. Recent work has shown that, by some relatively minor variations in the conditions of irradiation, the photochemical transformation of provitamin D may take a different course and give rise, by a modification of the ring system, to a substance known as an anthrasteroid, which has a structure not far removed from that of a carcinogenic hydrocarbon of the benzanthracene group. To the chemical mind there is no difficulty in imagining photochemical conversion of provitamin D to a chemical carcinogen. But again I am being fanciful and am speculating about changes which might well take place but for which there is no direct evidence.

Conclusion

I think, however, that I am on fairly safe ground in suggesting that, for some time to come, the study of chemical carcinogens is likely to prove one of the most profitable forms of cancer research and to give increasing insight into the nature of malignant change. Such lines of investigation will not necessarily point the way to cancer cures; but, if we can achieve a better understanding of the nature and origins of cancer, there is a good chance that, just as with industrial forms of cancer, the way may be open to prevent the onslaught of this great enemy of mankind. The road may be hard and long, but the impressive advances of knowledge of cancer in the past half-century give good grounds for hope that the goal may eventually be reached.

RESPONSE TO ALCOHOL IN CHRONIC ALCOHOLICS WITH LIVER DISEASE*

CLINICAL, PATHOLOGICAL, AND METABOLIC CHANGES

The clinical association between liver disease, chronic alcoholism, and malnutrition is accepted, but the relationship of any one of these factors to the others remains unresolved.

There is a geographical correlation between the incidence of human malnutrition and cirrhosis; and diets lacking lipotropic substances, particularly choline and methionine, will induce fatty change and fibrosis, similar to those in the human liver, in laboratory animals

(Himsworth 1950) Attempts to extend these observations to the treatment of liver disease in alcoholics with such agents have been unsuccessful (Phillips and Davidson 1954), although Patek and Post (1941) showed that a diet high in protein, calories, and vitamins, together with rest in bed and abstention from alcohol, produced clinical improvement Later work, however, showed that recovery was also possible with a relatively low intake of protein (Klatskin and Yesner 1949), thus emphasising the importance of abstention from alcohol and of a hospital regimen

An action specific to alcohol and leading to the appearance of fat and fibrosis in the liver has not been established in either man or other animals, but it has been shown that alcohol enhances the toxic effect of certain agents on the liver of laboratory animals (Rosenthal 1930) It has therefore been postulated that hepatic disease results from the combination of excessive alcohol intake and dietary deficiency Results of experiments on animals further indicate that the high caloric content of alcohol may increase the demand for lipotropic substances and thereby lead to pathological changes in the liver despite an otherwise adequate diet (Best et al 1949) Reports on the effect of alcohol in human patients with liver disease are limited to the observations that the addition of alcohol to the diets of 1 inpatient (Volwiler et al 1948) and 4 outpatients (Patek and Post 1941) did not interrupt their satisfactory progress

The characteristic protein malnutrition of the alcoholic has been related to economic factors and pathological changes in appetite, but calories derived from alcohol do not spare nitrogen in animals on low-protein diets (Mitchell and Curzon 1940), and the same action may operate in man

In an attempt to elucidate further the relationship between liver disease, alcoholism, and malnutrition we allowed alcohol to 7 patients already exhibiting these features Their intakes of protein were 25–65 g daily in the presence of adequate calories Some of the patients had calories derived from alcohol added to their diet, but others were maintained on an isocaloric regimen Nitrogen balances were recorded, and the effect on the course of the liver disease was followed by liver biopsy and serial liver-function tests

Material

Observations were made on 7 patients (6 male and 1 female) aged 33–67 (table I)

All the patients had been either unemployed or doing casual work in bars or restaurants, and the 5 married patients were either divorced or living apart from their spouses Their domestic environment was always unsatisfactory, and their nutritional histories revealed that, apart from alcohol, sandwiches were the main source of food during periods of drinking The female patient (case 1) was reluctant to divulge her alcoholic habits, whereas the other patients admitted drinking heavily for 20–40 years Cases 2 and 3 indulged in prolonged sprees, but cases 4–7 were steady drinkers The confessed intake is exemplified by case 7 (10 cans of beer and 7 shots of whisky daily) and case 6, whose preference for wine led to a daily consumption exceeding 5 quarts Except case 1, all the patients gave a history of "shakes," "jitters," "cold sweats," "dry heaves," or other disorders incident to alcoholism, and case 6 admitted previous hospital treatment for delirium tremens and "rum fits"

There was no history suggesting hepatic disorder until the period just before admission to hospital, but every patient had clinical signs of liver disease 4 patients (cases 3, 5, 6, and 7) were icteric, and 3 (cases 2, 4, and 6) had ascites on admission, but alcohol was not given until these complications had improved Liver biopsy revealed portal cirrhosis and fatty infiltration in 5 patients (cases 1, 3, 4, 5, and 7), cirrhosis without fat in case 4, and fatty vacuolisation without fibrosis in case 3

Muscle mass was reduced in all the patients, and in 5 (cases 1, 2, 5, 6, and 7) peripheral neuritis was the cause of admission to hospital, being sufficiently severe either to cause gross abnormality of gait or to prevent walking unaided Case 5 had mild Korsakoff psychosis and stigmata of recent scurvy

Methods

The patients were up and about in the ward of the Thorndike Memorial Laboratory, and their weight, temperature, pulse rate, and output of fæces and urine were recorded daily After a period of equilibration on the prescribed diet the patients were studied during an 8 day control period, during alcohol consumption, and for 8 days after the alcohol had been withheld Biochemical determinations and liver biopsies were done on the last day of the initial control period and when the alcohol was withheld Liver biopsies were made at about the same site in each patient with a Vim Silverman needle The histological interpretation of these specimens was undertaken by an independent observer, Dr D Campagna Pinto, of the Mallory Institute of Pathology, to whom we are most grateful

Diets and Alcohol Consumption

The daily diets contained adequate calories (2800–2285) and multivitamin supplements † The calculated content of protein was 25–65 g daily, and, on analysis, the diets contained 4 0–10 9 g of nitrogen

After the initial control period alcohol was given as 95% ethyl alcohol in fruit juice in divided doses six times daily for 10–32 days The total daily intakes of alcohol were 90–120 ml Alcohol was added to the caloric intake in 3 patients (cases 1, 2, and 4), and 3 patients (cases 3, 5, and 6) were kept on an isocaloric regimen by the deduction of carbohydr m the diet during the treatment with alcohol 7 the carbohydrate equivalent of rather less caloric value of the alcohol v thheld

---

† 'V ules' pro tories ork. the of

Nitrogen Balances

Nitrogen balances were studied in every patient except case 1 After the period of equilibration either 2-day or 4 day specimens of urine and of fæces were collected throughout the study and analysed for total nitrogen content

Biochemical Methods

Liver-function tests were made by methods reported earlier (Phillips and Davidson 1954) Blood-alcohol levels were determined by the technique of Conway (1950) and total nitrogen contents of diets, urine, and fæces by standard Kjeldahl procedures Starch tolerance tests were made in 2 patients by the method of Althausen and Uyeyama (1954)

Results

General Observations

The consumption of alcohol appeared to have no adverse effect on the clinical condition of any patient Case 5 developed pyrexia (102°F) with increasing jaundice during treatment with alcohol but recovered during continuation of the regimen, and a similar episode occurred several days after alcohol had been withheld Mild pyrexia (99–100°F), considered to be related to the liver disease, was present in 5 patients during the initial control period In every instance the body-temperature fell gradually towards normal either before or during treatment with alcohol

The effect of alcohol on the appetite was striking At the beginning of the study anorexia was usually severe, and difficulty was experienced in keeping the dietary intake constant at this stage in 4 patients (cases 3, 5, 6, and 7) The addition of alcohol to the diet led to rapid improvement in appetite, regardless of the total caloric intake, in every patient This increased desire for food continued after alcohol had been withheld, by which time the general condition had improved

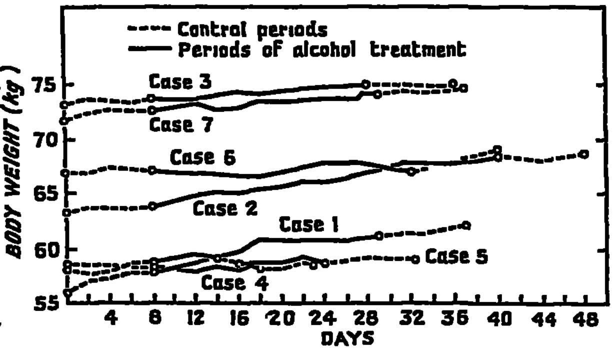

Fig 1—Alterations in body weight in relation to diet and consumption of alcohol

Most of the patients were more alert, euphoric, and cooperative during treatment with alcohol There was no evidence of gross inebriation, but intermittent drowsiness (cases 5 and 6) and unsteadiness of gait (cases 2 and 6) were observed Case 7 exhibited mild withdrawal symptoms—tremor, with disordered speech and behaviour —when the alcohol was withheld

In cases 5 and 7 the size of the liver, assessed by physical examination, became smaller during alcohol consumption and all the patients with peripheral neuritis (cases 1, 2, 5, 6, and 7) steadily improved in muscle power and gait

Body weight and Nitrogen Balance

Alterations in body-weight in relation to the administration of alcohol are shown in fig 1 3 patients were on an isocaloric regimen, receiving either 25 or 60 g of protein daily, and there was no significant change in weight in 2 of them (cases 5 and 6) The 3rd patient (case 3), whose diet contained 25 g of protein daily, gained 1 2 kg during a 21 day course of alcohol, but this was in proportion to his weight gain during the initial control period

* Starch tolerance tests also made before and after consumption of alcohol

3 patients whose diet contained 60–65 g of protein daily received the calories from alcohol in addition to those derived from the diet Case 2, whose weight was relatively constant before and after treatment with alcohol, gained 3 6 kg during a 32-day course of alcohol Case 1's weight increased rapidly during the initial control period and continued to do so when alcohol was added, but the rate of increase diminished as time progressed and was not clearly related to the alcohol alone In contrast, case 4's weight remained constant before, during, and after alcohol was given

During alcohol consumption case 7's intake was increased by 370 calories, rather less than the equivalent of the alcohol he received, and in the 3 week period he gained only 1 4 kg , an increase similar to that occurring before and after alcohol was allowed

The increases in weight of these patients were most closely related to the total calorie content of their diet (table I) and were greatest in cases 1 and 2, who received 3350 and 3400 calories respectively Except case 4, the patients who gained little or no weight were those on smaller caloric intakes The capacity to gain weight was not related to the severity of liver disease judged by liver-function tests (table II) and histological appearances (table III)

There was no evidence that alcohol consumption had any constant or significant effect on nitrogen balance (table IV) The retention of nitrogen was greatest in patients receiving the larger amounts of protein, and the balance was barely positive in cases 3 and 6, who were given only 25 g of protein daily These findings were comparable in each patient before, during, and after consumption of alcohol The retention of nitrogen was not increased by increasing the caloric intake with alcohol in 3 patients (cases 2, 4, and 7), nor was it greatly altered during alcohol administration in patients maintained on an isocaloric regimen (cases 3, 5, and 6)

Urinary loss of nitrogen was definitely greater in case 5 and smaller in cases 3 and 4 during consumption of alcohol, but little change was observed in the remainder Similarly, the nitrogen content of the fæces was usually

unaffected by alcohol consumption, but it was smaller in case 5 and larger in case 4

Biochemical Changes in Relation to Alcohol Administration

Liver-function tests were made immediately before and after the course of alcohol in every patient (table II) In no case was there any deterioration, and in most cases clear evidence of improvement was obtained

Serum bilirubin levels either fell or remained unchanged in every patient, but values above 1 0 mg per 100 ml were present initially in only cases 2 and 5 Case 5 developed pyrexia with hepatic enlargement and increasing jaundice (serum-bilirubin level rising from 1 5 to 8 5 mg per 100 ml) 5 days after the administration of alcohol Alcohol was omitted for 2 days, by which time the serum-bilirubin level had fallen to 5 1 mg per 100 ml , and the alcohol was then resumed Clinical improvement continued , and, when alcohol was finally withheld, the serum bilirubin level *had fallen to 1 1 mg* per 100 ml We therefore considered that the deterioration shown by liver function tests was unrelated to the consumption of alcohol, and this was supported by the onset of a second brief episode of pyrexia and jaundice (serum bilirubin level 7 1 mg per 100 ml) 5 days after alcohol had been withheld

Serum albumin levels either rose or remained relatively unchanged in every patient during consumption of alcohol, whereas *serum-globulin* levels fell in 2 patients (cases 1 and 4) and rose in 3 others (cases 5, 6, and 7) *Flocculation tests* were unchanged in 3 cases but were less strongly positive after consumption of alcohol in 4 patients (cases 2, 3, 5, and 6) The retention of bromsulphalein was less after alcohol administration in every patient, strikingly so in 3 patients (cases 5, 6, and 7)

Improvement in *liver-function tests* was greatest in patients in whom they were most grossly abnormal initially (cases 2, 3, 5, and 6) and was unrelated either to the constitution of the diet or to the dosage of, and duration of alcohol administration

Pancreatic function before and after the course of alcohol was assessed in 2 patients (cases 1 and 7) by the starch-tolerance test, and no change was observed Similarly, there was no change in the levels of *sodium potassium, chloride, and non-protein nitrogen in the serum* in relation to the consumption of alcohol in any patient *Blood-alcohol* levels, determined in 4 patients, were 17 0–46 5 mg per 100 ml

Hepatic Histology in Relation to Alcohol Consumption

Histological abnormalities in the liver were present in every patient and, except in case 5, liver biopsy was done both immediately before and after the treatment with alcohol (table III)

The gross abnormality of liver pattern always remained unaltered, and the degree of portal fibrosis and infiltration was usually the same, although both appeared greater in case 4 On the other hand, less portal fibrosis was *observed in the second biopsy in case* 1, and cellular infiltration of the portal space became less obvious in case 2 The proliferation of bile-ducts was less after the course of alcohol in 2 patients (cases 2 and 6) and a less striking decrease was seen in case 1, but it was unaffected in the remainder

Changes in the liver lobule during *alcohol consumption* were more striking Fat was present in 5 of the patients who had biopsies before and after alcohol The amount of fat, judged histologically, was clearly less after alcohol in 4 patients (cases 1, 2, 6, and 7) and appeared to be less in case 3 Alcoholic hyaline (Mallory 1911) was greatly reduced and liver cell necrosis *no longer* evident after alcohol in the patient who presented *these* abnormalities (case 2) Polymorph infiltration was present initially in 4 patients and decreased after alcohol in 2 of them (cases 2 and 6) but remained unchanged in the others (cases 1 and 7) Nuclear abnormalities of the liver-cells were present in every patient, but after alcohol they were less obvious or no longer apparent in 3 patients (cases 3, 6, and 7) and unaffected in the other 3 patients

* Diet isocaloric throughout study

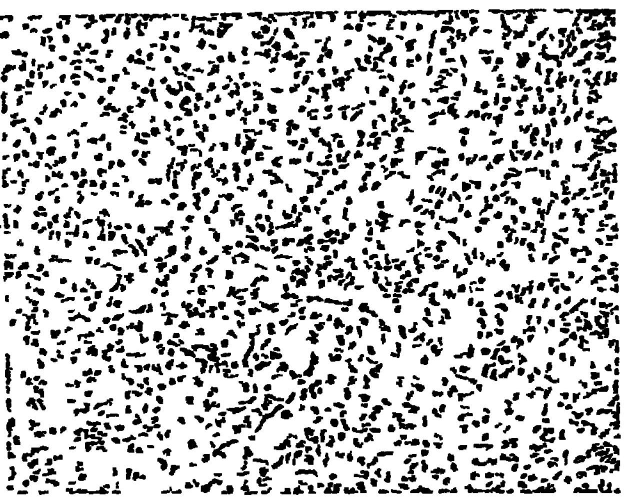

Fig 2—Case 2 liver biopsy before administration of alcohol (× 158)

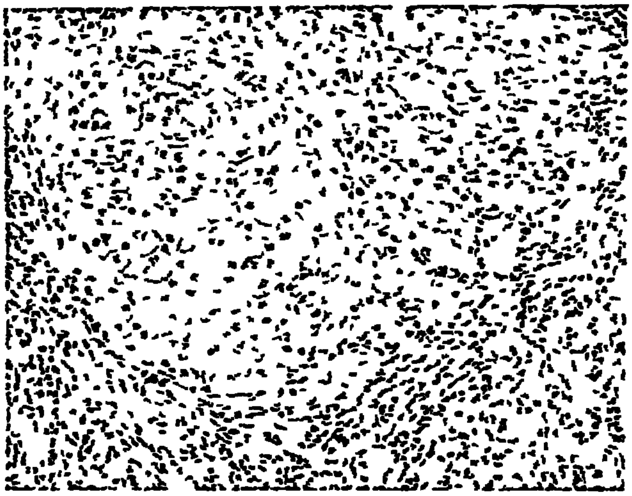

Fig 3—Case 2 liver biopsy after administration of alcohol (× 158)

The best-defined improvements in histological appearances were found either in patients who received the longer courses of alcohol, with consequently a greater interval between the two liver biopsies, or when the initial changes were most severe Case 2 who received the larger daily intake of alcohol for the longest period (32 days) exhibited the greatest degree of improvement (figs 2–5), whereas case 4 had a short course of alcohol with little alteration in histological findings The pathological changes, particularly the fatty infiltration, could not be related either to the caloric intake or to the protein content of the diet

Discussion

In no patient was an adverse metabolic effect attributable to consumption of alcohol Most of the patients improved clinically, with corresponding changes in liver-function tests and histology The rate of recovery in these respects was comparable to that reported by Volwiler et al (1948) in response to diets high in protein and calories together with abstention from alcohol, but the possibility cannot be excluded that improvement may have been delayed by alcohol in our patients in a degree too subtle to be appreciated in the absence of controls

The most striking clinical effects of alcohol were the increased appetite and the euphoria that immediately followed its addition to the regimen These facts suggest that small doses of alcohol should be given therapeutically to alcoholics with liver disease, because the anorexia which often complicates their management may be due to abstention from alcohol Alcohol did not impede the improvement of peripheral neuritis as Strauss (1935) has shown earlier, and the liver became smaller during treatment with alcohol in 2 patients 1 of whom also recovered simultaneously from jaundice The increases in body-weight suggest that the alcoholic with liver disease can use calories from alcohol in the dosage given and possibly in larger dosages (Newman 1949), although they may not be directly available as a source of muscular energy (Mitchell and Curzon 1940)

Nitrogen balance was more clearly related to the protein intake than to the calories consumed or to the severity of the liver disease It was maintained with difficulty if at all on the diet containing only 25 g of protein but these patients made satisfactory progress The addition of alcohol did not influence the nitrogen balance: this fact supports the view that the protein malnutrition of alcoholism is an expression of dietary deficiency alone In particular, there was no evidence of an effect of alcohol on pancreatic function, because the nitrogen content of the fæces remained constant and, in 2 patients thus studied, starch-tolerance tests were unaffected

Derangement of liver function tests and hepatic histology was usually diminished after alcohol administration Although there was a poor relationship between the biochemical and pathological changes the degree of

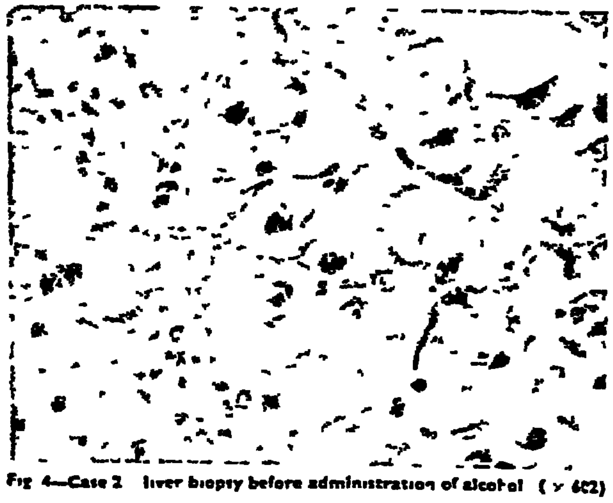

Fig 4—Case 2 liver biopsy before administration of alcohol (× 402)

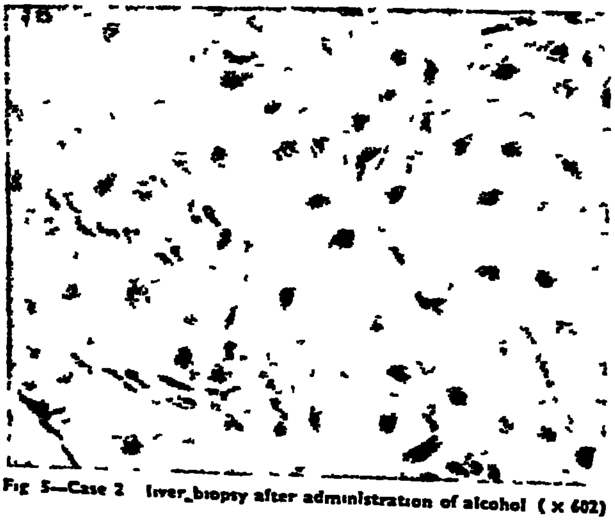

Fig 5—Case 2 liver biopsy after administration of alcohol (× 402)

improvement in both was related more closely to the severity of the initial abnormalities and to the length of time between observations than to the constitution of the diets Thus the lack of alteration in the amount of portal fibrosis during treatment with alcohol was attributable to the short duration of the study, whereas the more acute changes of cellular infiltration, alcoholic hyaline, and either necrosis or nuclear abnormalities of the liver-cells diminished or disappeared Excess fat in the liver decreased after alcohol was given The cause of fatty vacuolisation is uncertain, but the results of experiments on animals relate the presence of fat to a high caloric intake from alcohol or from sucrose in the absence of adequate lipotropic substances (Ashworth 1947, Best et al 1949) Klatskin et al (1954), confirming that alcohol increases the choline requirement, considered that the effect was independent of the caloric intake In our patients fat disappeared from the liver regardless of the total intake of calories or of alcohol and when the diet was marginal in protein content, although not necessarily so in lipotropic factors However, patients on a diet devoid of protein do not show any convincing diminution in liver fat (Phillips et al 1952), and it is therefore possible that the limitation of protein and the intakes of calories and alcohol used in this study were insufficient to delay significantly improvement in hepatic histology

The factors of importance in the genesis of liver disease in the chronic alcoholic consequently remain obscure No clinical or pathological improvement takes place during rest in bed with adequate calories, minerals, and vitamins, and abstention from alcohol (Phillips et al 1952), even when choline is added to the regimen (Phillips and Davidson 1954) Recovery may be initiated, however, by relatively small amounts of protein in the diet (Gabuzda and Davidson 1954), and we confirmed this

The consumption of alcohol may be a determining factor in deterioration of liver function, but we did not find any adverse clinical, pathological, or metabolic effect, even on marginal intakes of protein Interpretation of our results demands recognition of the differences that existed between the hospital regimen and the way of life normally pursued by these patients Although the amount of alcohol given was in most cases equivalent to half a pint of spirits daily and exceeded that prescribed in similar circumstances by earlier workers (Patek and Post 1941, Volwiler et al 1948) it was nevertheless smaller than that to which many such patients have become accustomed Similarly, even the low-protein diets given in hospital were probably more adequate than the food usually taken during periods of drinking On the other hand, the alcohol consumed was more than sufficient to satisfy the criteria of chronic alcoholism in liver disease (Olsen 1950), and nitrogen balance was precarious on the diets containing the least amounts of protein Furthermore, it may be argued that any deleterious effect of alcohol and dietary deficiency should have been rapidly apparent in these patients, because malnutrition and hepatic disease were already established

We therefore conclude that, if a combination of alcohol and dietary deficiency contributes to liver disease in the chronic alcoholic, it is in excess of what can reasonably be reproduced in a study of this nature

Summary

7 chronic alcoholics with liver disease and malnutrition were given 90–120 ml of 95% ethyl alcohol daily

The protein content of the diet varied from 25 g, on which the nitrogen balance was marginal, to 65 g daily The diet of 3 patients was kept isocaloric, but the remaining 4 patients received alcohol in addition to the previous caloric intake

Consumption of alcohol was accompanied by euph
and increased appetite

Increased body-weight showed that calories fr
alcohol could be used by these patients, and nitrog
balances were not changed by alcohol

Liver biopsies and biochemical liver function tests d
not reveal any adverse effect of alcohol

If alcohol alone or in combination with inadeq
protein nutrition contributes to liver disease in th
alcoholic, these factors are greatly in excess of th
reproduced in this study

Alcohol may have a place in the treatment of alcohol
with liver disease

We are grateful to Miss E Antonaros and Mrs M F Bradley for dietetic assistance, to Miss A N Ballou and M E A. Hirshberg for the biochemical determinations, a to Miss L Leavitt for the histological preparations

ACUTE POLYNEURITIS TREATED WITH CORTISONE

G S GRAVESON

M A, M D Camb, M R C P

CONSULTANT NEUROLOGIST, SOUTHAMPTON GENERAL HOSPITAL

THE cause of the disease, variously called acute tox febrile, or infectious polyneuritis, or the Landry Guill Barré syndrome, has never been established with a certainty Its frequent occurrence as a sequel to so non specific febrile illness was originally thought t indicate that the peripheral nervous system was dama by some toxic or infective agent, though none h been isolated from pathological material In recent y the concept of the disease as an allergic manifesta has steadily been gaining ground One of the first suggest this was Furtado (1950) He argued that its clinical manifestation as a "second illness" occurr within narrow time limits after a primary infection a the characteristic changes in the protein content of t cerebrospinal fluid (C S F) could best be explained b regarding it as a "peripheral form of neuro allerg He thought, too, that there might be a relation between this illness, secondary to some unknown infection, and those types of polyneuritis complicat known infections, such as diphtheria and glandular fev or the introduction of foreign proteins, such as injecte serum

At the same time fresh histological studies wit modern techniques have shown that the patholog changes in the disease are not those of a primary infla mation Haymaker and Kernohan (1949), in a mo extensive and impressive review of the subject base on the findings of fifty fatal cases, showed that, for th first 3 or 4 days of the illness, the only change was œdema of the nerve roots This was followed by d integration of myelin sheaths and axis cylinders only in the 2nd week of the illness did a cellular reacti evelop. Much the same findings were reported by cheinker (1949), who thought that the œdema of the ots caused paralysis by mechanical constriction of e radicular nerves at their points of penetration of the pinal meninges.

Final proof that polyneuritis can be allergic in origin s provided by the interesting experimental work of aksman and Adams (1955).

They have produced in rabbits, by injecting homologous r heterologous sciatic nerve tissue plus an adjuvant (tubercle acilli), a polyneuritis comparable to the human disease. his condition occurred about 14 days after inoculation, and rogressed rapidly for about 3 days, after which, if the rabbit urvived (as it usually did), a rapid and more or less complete ecovery ensued. As in the Landry-Guillain-Barré syndrome, he polyneuritis was associated, in most cases but not all, ith a rise of protein as the only change in the C.S.F. Pathoogically, lesions were found in spinal roots, ganglia, and erves. Myelin sheaths and axis cylinders degenerated, and here was a cellular infiltration; but which came first, in uch a brief and intense reaction, it was difficult to be certain about.

Waksman and Adams compare this condition to experimental allergic encephalomyelitis produced by the injection of brain or cord tissue with adjuvants and known to be due to an immunological reaction.

Such, then, is the evidence supporting the hypothesis that acute toxic polyneuritis is an allergic disease and providing the rationale for its treatment with cortisone and corticotrophin (A.C.T.H.). First reports of its use were unfavourable. Shy and McEachern (1951) and Merritt (1952) each recorded, without detail, three cases which did not respond. Since 1952, however, cases have been described in which cortisone or corticotrophin halted the disease or even produced dramatic improvement and early cure (Stillman and Ganong 1952, Seltzer et al. 1952, Blood et al. 1953, Newey and Lubin 1953, Drenick and Arol 1953, Senseman and Greenstein 1953, Plum 1953, Vernon 1954, Guiang and Leones Guiang 1954, Luzes 1954, Tupper and Foster 1954, Guichard et al. 1955).

In this country the only recorded case is case 3 of Clarke et al. (1954): cortisone was given to a man apparently in extremis with respiratory paralysis and cardiovascular failure, and he slowly recovered. These workers felt that the use of cortisone merited further investigation, and thought it especially indicated in cases pursuing a relentless course and those with respiratory failure or hypotensive cardiovascular collapse. Yet if allergy is the underlying basis of the disease and structural changes in peripheral nerves follow œdema, it seems more rational to use cortisone at the earliest possible opportunity before severe damage has been done to the nerves. It might then be expected to act rapidly and effectively, whereas, once nerve fibres have been destroyed, no treatment is likely to hasten the normal process of repair. In this paper I attempt to show that such results are usually achieved in practice.

Clinical Study

In the past two years seven patients with acute toxic polyneuritis have been treated with cortisone. One patient (case 2) had two attacks. All showed the usual features of a symmetrical muscular weakness of varying severity associated with loss of tendon-reflexes, an increase of muscle tenderness, and peripheral sensory symptoms with or without objective sensory loss. All except case 2 had an increase of protein as the only abnormal change in the C.S.F. Four (cases 1–4) are regarded as mild cases, and three (cases 5–7) as more severe—though none were exceptionally severe for respiratory failure did not occur. All were given cortisone as soon as the diagnosis was established. The dosage used for cases 1–5 was 100 mg. daily for 2 days, 75 mg. daily for 2 days, and then 50 mg. daily for 10 days. The experience of case 6, however, showed that this schedule was insufficient for severer cases. Case 7 was therefore given 300 mg. daily for 2 days, then 200 mg. for 2 days, and 100 mg. daily thereafter.

Mild Cases

Case 1.—A boy of 14 was admitted to hospital on the 8th day of illness, complaining of progressive weakness of both arms and legs, with tingling in his fingers and feet.

Examination showed moderate generalised weakness of all muscle groups in his legs. He could stand and walk only with difficulty; knee and ankle jerks were absent, and plantar responses were flexor. Tenderness of the calves was increased, but there was no demonstrable loss of superficial or deep sensation. In the arms deltoid, biceps, triceps, and finger extensor muscles were weak. Biceps jerks were sluggish, other arm reflexes were absent. There was slight bilateral facial weakness. The C.S.F. contained protein 400 mg. per 100 ml.

Cortisone was given on the day of admission and continued for 14 days. After 7 days there was no change in his condition and no new symptoms had arisen. In the 2nd week, however, he made a very rapid recovery, and by the 14th day his arms were normal except for fractional weakness of the triceps, and his legs were normally strong except for slight weakness of the toe and ankle extensors. He was then allowed to go home. A month later he had fully recovered.

Case 2.—A woman of 34 was first seen on Oct. 11, 1955, giving 4 weeks' history of shooting pains in her lower legs, with numbness and tingling in her feet, spreading up to her calves. Walking had become difficult, and she felt unsteady.

Examination showed a weakness of hip flexors, ankle dorsiflexors, and toe extensors and flexors in the legs, and of deltoid, biceps, and triceps in the arms. All tendon reflexes were absent. Calf tenderness was increased and vibration sense lost at the ankles, but there was no loss of superficial sensation. The C.S.F. was normal (protein 10 mg. per 100 ml.).

Cortisone was given for 2 weeks. As in case 1, there was no change after 7 days, but improvement was rapid in the 2nd week, and after 14 days muscular power was normal in her limbs and she was symptom free.

She remained well until June, 1956, when her symptoms recurred and slowly progressed until she was seen 6 weeks later. By then her walking was unsteady and she had continuous tingling over the legs below the knees and from the mid forearms distally. In the arms all muscle groups were weak, but there was no sensory loss. In the legs weakness affected the hip flexors and all muscles below the knees. Superficial sensation to pain and touch was diminished almost up to the groins, and muscle tenderness was increased. She was treated at home with cortisone for 2 weeks. By then the only remaining signs were a very slight weakness of triceps and hip flexors and the persistence of increased calf tenderness. These improved spontaneously without further treatment during the next month. Her tendon reflexes remained absent after her first attack.

Case 3.—A woman of 56 was admitted to a surgical ward on Nov. 1, 1955, for treatment of hiatus hernia. During the previous 3 weeks she had had increasing weakness of her arms and legs to a point where she could no longer walk, and also continuous tinglings in her hands and feet.

When I saw her on Nov. 8 she showed a moderately severe weakness of all muscle groups in both arms and legs, though no group was completely paralysed. Tendon jerks were absent in the legs and diminished in the arms; muscle tenderness was increased, and she had hyperalgesia over her soles. The C.S.F. contained protein 100 mg. per 100 ml.

She was transferred to a medical ward, and cortisone treatment was started on Nov. 13—i.e., 5 weeks after the onset of her symptoms. There had been no progression in the week before treatment began. Improvement began within 48 hours and continued rapidly and steadily until, at the end of the 2 weeks' course, no residual weakness or sensory signs were found.

Case 4.—A man of 56 was admitted to hospital on Feb. 25, 1956. 2 weeks previously he had had a transient feverish illness with aches and pains in his limbs and back. He stayed in bed for a day. 5 days later his legs felt weak while he was out walking, and later that day he found he could not use his fingers properly. This limb weakness had increased slightly, but he was still able to walk. There was no tingling or numbness in his extremities.

Examination showed a slight bifacial weakness; in the arms a weakness of biceps, triceps, forearm, and hand muscles;

in the legs weakness of hip flexors and all muscles below the knees The arm reflexes and the ankle jerks were absent, the knee-jerks sluggishly present Calf tenderness was increased There was no sensory loss The C S F contained protein 90 mg per 100 ml

Cortisone treatment was started on Feb 26—i e, 10 days after the onset of his polyneuritis After 3 days improvement in power was obvious, and this continued steadily until, after 2 weeks' treatment, he had completely recovered

Severe Cases

Case 5.—A man of 64 was first seen on May 1, 1956 His illness had started 17 days previously with tingling over the soles of his feet 2 days later his legs became weak and he fell at work Thereafter progress was rapid, and within 10 days of the onset he was unable to walk and had developed paræsthesiæ in his hands

Examination revealed profound weakness of his legs He could raise his right leg two inches off the bed and the left one inch Toe movements were flickers only Tendon jerks were absent, calf tenderness increased, joint sense impaired in the feet, and superficial sensation diminished below the knees In the arms all muscle groups were affected but only moderately, no muscles being completely paralysed Touch and pain sense were impaired below the level of the wrist joints The C S F contained protein 55 mg per 100 ml

Cortisone treatment was started on May 1 After a week his arms were stronger but his legs showed no change After 2 weeks power in his arms was normal save for fractional weakness of the triceps, and sensation had recovered, though he still had tinglings in his fingers He could lift both legs two feet off the bed, but there had been no recovery in muscles below the knees He was then transferred to a hospital nearer his home, where through a misunderstanding cortisone treatment was continued, 50 mg daily, for another month By this time he had no symptoms in his arms, his thigh muscles had recovered fully, but his lower leg muscles were still moderately weak After another 4 weeks—i e, 10 weeks from the onset of treatment—he had completely recovered

Case 6.—A man of 40 was seen on June 2, 1956 A week previously he had been slightly unwell for a day, with headache and pains in the back, which he had put down to a feverish cold On May 30 he complained of stiffness in his legs and tingling in his fingers and toes, and these symptoms became worse

Examination on June 2 showed minimal signs There was just detectable weakness of hand muscles, hip flexors, and toe extensors, tendon reflexes were diminished but not absent, calf tenderness was severe, and there was a little blunting of sensation over his feet His C S F contained protein 450 mg per 100 ml

Cortisone treatment was started on June 3 In the next 3 days his condition deteriorated slightly, weakness becoming slightly more evident in the muscles originally affected and also now involving deltoid, biceps, triceps, and toe flexors on each side, and the facial muscles 2 days later slight improvement was evident in arms and legs, and on this day the dose of cortisone was reduced to 50 mg daily (after 3 days on 100 mg and 3 days on 75 mg daily) 2 days later (June 10) he was much worse, with generalised weakness of face, arms, and legs loss of reflexes, and sensory loss over feet and hands He remained in this state for 10 days before improvement was first noted in arm muscles and face

Cortisone was continued (50 mg daily) for a further 10 days until June 30 By this time his arms and face had improved considerably but his legs less so He was discharged home 2 weeks later (July 14), by which time his face was normal, only weakness of finger muscles remained in the arms and he could stand and walk with assistance, though all groups of leg muscles were still weak A month later he had completely recovered his illness having lasted 10 weeks

This patient was the only one of the series who did not respond to cortisone In retrospect it was felt that dosage had been inadequate and that this was why he rather suddenly deteriorated when it was reduced

Case 7.—A woman of 69 was transferred on Oct 11, 1956, from another hospital, to which she had been admitted 11 weeks previously with a fracture of the neck of the left femur This had been pinned and plated and was healing satisfactorily She had begun to get about on crutches, avoiding weight bearing on the left leg when about 6 weeks before transfer she noticed that walking was becoming difficult Gradually her legs became weaker until she could not move them, her fingers became feeble, and she developed at the same time tingling in fingers and feet

On admission her legs were completely paralysed except for feeble movement of the hip flexors, and the arm muscles were all weak, but the finger flexors and intrinsic hand muscles were much more severely affected than other groups Arm reflexes were diminished, leg reflexes absent Muscle tenderness was increased Joint sense was impaired in the fingers and lost in the toes, but there was no alteration in skin sensation Her C S F contained protein 140 mg per 100 ml

She was given cortisone 300 mg daily for 2 days then 200 mg daily for 2 days, and then 100 mg daily thereafter After a week weakness in the arms was confined to finger flexors and hand muscles In the legs there was still no movement below the knees, but muscles in the thighs were seen contracting After 2 weeks hand and finger muscles were improved but not normal, and there had been a further slight improvement in the legs, with a flicker of contraction in the left toe extensors Cortisone treatment was then stopped (Oct 28) 3 days later slight weakness had recurred in biceps, triceps, and wrist extensors, and there was no contraction in the left toe extensors She was then (Nov 1) given 200 mg daily for 2 days and then 100 mg daily After 4 days power had returned to these arm muscles, and they were normal again

Cortisone was continued for 2 weeks and then stopped (Nov 14) By that time she still had some weakness of the interossei in the hands, but they were much stronger She could lift her legs well in the air, and the quadriceps, hamstrings, and calf muscles were quite strong, but there were only flicker movements of toe and ankle dorsiflexors and no movement in the peroneal group There was no further relapse thereafter, and she slowly improved, though her recovery was not yet complete 7 weeks after the beginning of treatment

DISCUSSION

The severity of these cases has been judged not by the extent of the distribution of muscle weakness but by the degree of paralysis in the muscles worst affected In the mild cases (cases 1–4) no muscles were completely paralysed, though paresis was moderately severe in some muscles in all four limbs The results of treatment in this group are summarised in table I They show that recovery was complete or almost so in all these cases after 2 weeks' treatment with a small dosage of cortisone The more severe cases (cases 5–7), summarised in table II are those in which some muscle groups were paralysed or reduced to flicker movement and others less affected

TABLE I—RESULTS IN MILD CASES

Case no	Sex	Age (yr)	Degree of weakness	Onset before treatment	C S F protein (mg per 100 ml)	After two weeks	Remarks
1	M	17	F + A + L +	10 days	400	F 0 A– + 90% L– + recovery	Improvement began in week
2	F	34	*1st attack October 1955* F 0 A + L +	4 weeks	10	F 0 A 0 L 0	Improvement in 2nd week
			2nd attack June 1956 F 0 A + L +	6 weeks		F 0 A– + 95% L– + recovery	
3	F	36	F 0 A + L +	3 weeks	100	F 0 A 0 L 0	Improvement began in week
4	M	56	F– + A + L +	10 days	90	F 0 A 0 L 0	Improvement after 3 days

F face A arm L leg
+ Diffuse weakness but no muscle group paralysed completely
+ + Diffuse weakness with one muscle group paralysed completely
+ + + Total or almost total limb paralysis

TABLE II—RESULTS IN SEVERE CASES

Case no	Sex	Age (yr)	Degree of weakness	Onset before treatment	C S F protein (mg per 100 ml)	After two weeks	Remarks
5	M	64	F 0 A − L −+−	17 days	55	F 0 A 0 L −	Improvement in 1st week Complete recovery in 10 weeks Cortisone continued for 6 weeks
6	M	40	F 0 A −− L −+	4 days	450	F − A −− L ++	Slight deterioration in first 5 days Much worse 2 days after reduction of cortisone Recovery after 10 weeks
7	F	69	F 0 A ++ L +−−	6 weeks	140	F 0 A + L −+	Improvement in 1st week

This group includes case 6, where deterioration occurred in spite of treatment ; this coincided with a reduction of the daily dose of cortisone, and treatment is thought to have been inadequate The two other cases in this group showed improvement after 2 weeks but of varying extent Muscles affected in these two patients to a similar degree as in the mild cases showed an equally good response and had by then completely recovered More severely affected muscles, however, were still very weak, and some had not begun to recover In case 7 a return of weakness followed within a few days of the cessation of cortisone therapy, but recovery was rapid when cortisone was given again It is clear from tables I and II that recovery is not related to the duration of the illness before treatment begins but only to the severity of the paralysis at this time In some cases improvement was apparent after a few days but in others it was not noticeable until the second week Except in case 6, no deterioration took place once cortisone had been given

It may well be thought that, in a disease whose severity and duration are very variable, these results are no better than chance would allow, especially as most of the patients had mild attacks The disease is so relatively uncommon that a control series would be impossible to obtain in a reasonable time , and therefore comparison has to be made with the reports of others not treated with cortisone The largest series in recent years is that of Crozier and Ainley (1955), who reviewed seventeen cases seen in 8 years Three patients died, and the period of recovery in the survivors varied between 1 and 4 months These figures show that the untreated disease, at best, lasts twice as long as when cortisone is given I have found no published report of any patient having died of the disease after cortisone was given

It seems justifiable, therefore, to conclude from this trial that cortisone is the remedy of choice in acute toxic polyneuritis but must be given as soon as possible and in adequate dosages If treatment is started before paralysis becomes severe, the chances of rapid improvement should be good Beyond this stage it should stop the disease from progressing, but the over-all recovery-time of completely paralysed muscles may not be shortened In view of the pathology of the disease we may suppose that, to be effective, it must be given when œdema of nerve roots is present and before structural changes have taken place For the average case the dosage suggested is 300 mg daily for 2 days 200 mg daily for 2 days, and then 100 mg daily for 10 days If, after withdrawal at this stage, deterioration occurs, further treatment for another week or more may be needed

In fulminating cases of the Landry type intravenous infusions of corticotrophin might well be more effective, but I have not yet had an opportunity to treat such a case

The results of cortisone treatment support the opinion that this disease is an allergic disturbance If further experience confirms this, the term acute allergic polyneuritis would be preferable to any of the various synonyms at present in vogue

Summary

Eight attacks of acute polyneuritis in seven patients were treated with cortisone

In only one case was the disease not promptly arrested and in this case the amounts of cortisone given were probably inadequate

In seven attacks recovery took place quickly within a period of 2 weeks in those muscles not severely affected—i e , mild cases recovered completely, and severe cases improved partially

Improvement is related to the severity of muscle weakness at the onset of treatment Hence very early diagnosis is necessary for successful therapy

I am grateful to Dr Wilfred Brinton for referring cases 5 and 6 to me

MASSIVE THROMBOPHLEBITIS

B N Catchpole
M B Manc , F R C S
LECTURER IN SURGERY UNIVERSITY OF SHEFFIELD

MASSIVE thrombophlebitis (massive venous thrombosis, phlegmasia cærulea dolens) may rapidly kill a patient by immobilising large amounts of fluid and blood in the leg Alternatively it may cause " stagnation " gangrene of the foot—a condition which may be confused with an arterial ischæmic lesion

Massive thrombophlebitis is by no means uncommon, but it is probably often misdiagnosed and wrongly treated I therefore report five cases, and discuss the physiopathology, differential diagnosis, and treatment

Case-reports

Case 1 —A woman, aged 65, complaining of abdominal colic with the passage of blood and mucus per rectum, was admitted to hospital 10 months after the onset of her symptoms There was a large tender mass in the left iliac fossa and left side of the pelvis Shortly after admission she developed a colovesical fistula. A transverse colostomy was performed and some 12 days later she developed a classic white leg " (phlegmasia alba dolens) on the left side The limb was raised initially and mobilised early , no anticoagulants were used

On the 21st postoperative day she suddenly complained of intense pain in her right leg This pain had reached its peak within 30 minutes and completely prohibited any movement, either active or passive

The limb was cyanotic from the inguinal ligament to the toes with abundant petechial hæmorrhages above and below

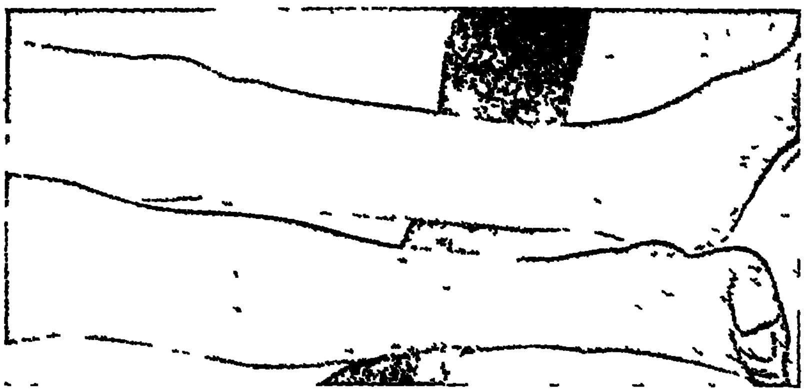

Fig 1—Case 1 three hours after onset of massive thrombophlebitis in right leg Left leg is recovering from iliofemoral thrombophlebitis A group of petechial hæmorrhages is ringed

the knee (fig 1) It felt cool, and no pulse distal to that of the femoral artery at the groin was palpable, the involved skin was grossly hyperæsthetic Intra arterial (femoral) tolazoline ('Priscol') 50 mg had no apparent effect on the condition of the limb Œdema developed rapidly, and the patient became shocked Transfusions of blood and of plasma did not arrest the fall of blood-pressure, and she died 16 hours after the onset of the pain

At restricted necropsy an abscess was found surrounding a carcinoma of the pelvic colon which had eroded into the bladder The left iliac veins were occluded by organising blood clot, the lowest three inches of the inferior vena cava and the right iliac veins were obstructed by recent adherent clot The corresponding arteries were patent

Case 2 —A woman, aged 34, in her 9th month of pregnancy, was admitted to hospital with œdema of the lower legs and hydramnios A stillborn anencephalic child was delivered 24 hours after artificial rupture of the membranes 15 hours after delivery anticoagulant therapy was started because œdema had spread to the inguinal ligaments During the next 3 days œdema persisted, but the circulation of the limbs was not impaired The patient then complained of tingling in the toes of her left foot, which became cold and dark blue œdema of the calf increased Pain in the first and second toes worsened, and within 12 hours they had become virtually black (fig 2)

The patient was then transferred to a vascular unit She was not shocked, there was no evidence of any arterial insufficiency in her feet, and peripheral pulses were present, but her left leg was still œdematous to the groin Anticoagulant therapy was stopped, and lumbar paravertebral block was performed—without benefit The swelling of the limb slowly resolved, and the necrotic areas of the toes were allowed to demarcate before being surgically removed, complete healing was slow The patient has since remained well but has to use elastic support to control the hydrostatic œdema of her left leg

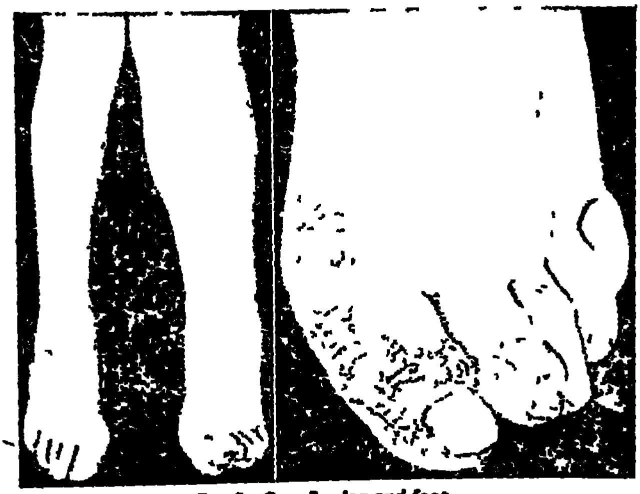

Fig 2—Case 2 leg and foot

Case 3 —A woman, aged 20, and 2 m pregnant, complained that for 4 mont had been passing multiple loose stools occasionally tinged with blood 2 weeks be admission she had had a cramp like pain the left ankle and calf preventing her fr bearing weight on the heel Œdema of t foot followed 4 days later, and the calf pa now bursting in character, was accompan by a deep ache in the thigh She next dev oped a cramp like pain in the right calf 4 days, there was no noticeable œdema the calf felt hard Both legs then began t improve

The patient was admitted to hospital investigation owing to continued diar and ulcerative colitis was diagnosed 3 da after admission severe pain, reaching a max imum in 15 minutes, recurred in the l thigh It spread slowly down the leg, wh felt as though it would burst The li was blue to the groin, showed turgid veins a rapidly swelled Over the next 4 days both the colour a pain of the limb improved 6 days after the onset of th episode she was woken at night by a burning pain in the foot, with severe paræsthesiæ in the toes, which became d cyanosed The foot swelled again, but toe movement was still possible Within 10 minutes the burning sensation began to go, but paræsthesiæ persisted in the second and third toes, which became gangrenous in their distal portions (fig 3)

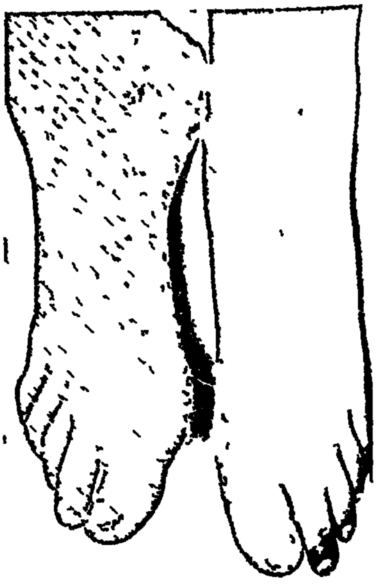

Fig 3—Case 3 staged development of mas thrombophlebitis has given rise to gangren terminal parts of second and third toes

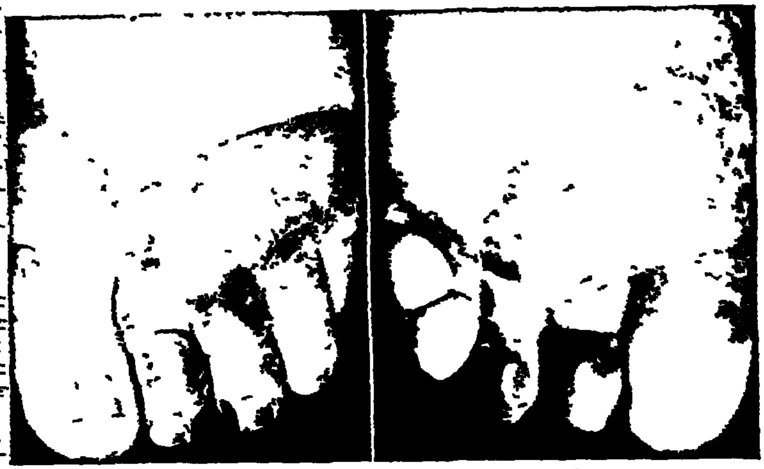
From the time when the left thigh was involved in hospital she was treated with anticoagulants, but in spite of this she had further attacks of phlebitis At no time, however, was she shocked Physiotherapy was begun when swelling had considerably subsided, dilated veins having developed aroun the root of the thigh and on the lower abdomen Th necrotic areas of the toes were allowed to separate spontaneously

Case 4 —A woman, aged 38, was admitted urgently t hospital, where on laparotomy a ruptured cystadenocarcino of the ovary with widespread pelvic metastasis was foun Immediately after the operation her right calf swelled, w pain on dorsiflexion of the foot and tenderness of the ca and the popliteal fossa

12 days after the operation she complained of a sh pain in the right chest and was found to have œdema of th left leg up to the groin Anticoagulant therapy was starte and morphine prescribed She had bloodstained sputum 24 hours later and two further episodes of acute pain in th right chest, after which these symptoms improved 8 day after the initial swelling of the left leg, however, there wa a sudden increase in œdema with severe pain and cyanosis of the whole limb Anticoagulants were continued, and wh she was seen 6 days after this episode, there were hæmorrhag blebs on the dorsum of the foot with gangrene of the secon and third toes (fig 4), ankle pulses were palpable Ant coagulants were stopped, and mobilisation was encouraged

The patient's general condition slowly improved in th next few weeks, before ascites and a rapidly advan



(a) (b)

Fig 4—Case 4 dorsal (a) and plantar (b) aspects of foot involved by massive thrombophlebitis.

achexia became obvious She was allowed home, where she ied of widespread metastatic disease 4 months after aparotomy No necropsy was performed

Case 5 —A man aged 67 had been losing weight and feeling eak for 3 months A recent pneumonia had caused his doctor o suspect carcinoma of the bronchus. On the morning of dmission to hospital the patient awoke to find his right leg wollen (fig 5) It continued to swell felt very heavy and as blue when he was admitted to hospital 7 hours after he first symptoms At no time did he feel any pain

On examination the limb was swollen from the toes to the ower abdomen and deep blue, with multiple petechial hæmorrhages (fig 6), particularly involving the thigh The œdema was hard, but ankle pulses were still palpable The terminal phalanges of the toes were hypoæsthetic The patient was enerally wasted, and several hard glands were palpable in he lower part of his neck 30 minutes after admission his pulse rate was 140 and systolic blood pressure 70 mm Hg An intravenous drip was immediately set up, and within 7 hours he had received two pints of blood and five pints of lucose saline solution Simultaneously vigorous passive exercise of the whole leg which was kept raised, was begun and continued for the first 12 hours in hospital The patient's general improvement was considerable, and the œdema of the leg began to soften.

2 days later his entire left leg became blue and began o swell his pulse rate rose and his blood-pressure again fell Intravenous fluids and elevation and exercise for this limb were started and produced immediate improvement No anticoagulants were used during either episode

Radiography revealed massive secondary deposits in the chest, bloody stools were passed and the patient went steadily downhill to die of cachexia 4 weeks after admission Necropsy showed a primary stenotic carcinoma of the pelvic colon with gross secondary carcinomatosis of his liver and lungs The inferior vena cava below the renal veins and all the pelvic veins were occluded by thrombus as far distally as the metatarsal veins

DISCUSSION

The symptoms of massive thrombophlebitis in a leg result from venous occlusion sufficient to cause nearly complete arrest of capillary blood flow This may occur as a solitary dramatic episode (e g cases 1 and 5) or as a result of a series of attacks of thrombophlebitis over a matter of days or even hours (e g, cases 2–4) The veins involved by the occlusion may be predominantly those carrying blood out of the limb at its root the small radicles at the periphery (Haimovici 1950) or both groups of vessels In whatever way this massive thrombophlebitis develops, the blood-flow through the capillary bed is eventually reduced while the arterial input continues to congest the tissues

Another consequence of the high capillary pressure is a considerable rise of capillary filtration, which leads to rapidly developing œdema The loss of circulating blood volume both in the congested vessels and by œdema fluid may be sufficient to produce fatal oligæmic shock (e g, case 1)

If after massive thrombophlebitis ischæmia lasts long enough gangrene results This is generally moist but occasionally dry (Haimovici 1950), it varies in extent and usually involves the distal part of the foot Gangrene of the thigh, however, has been described (Hershey and Snyder 1953)

The ætiology of massive thrombophlebitis seems to be similar to that of the less extensive form (white leg phlegmasia alba dolens) Massive phlebitis in the leg is often associated with inflammation or neoplastic disease of the pelvis and this was so in all the present cases Nevertheless it has been known to develop in an apparently healthy young man (Halligan et al 1953)

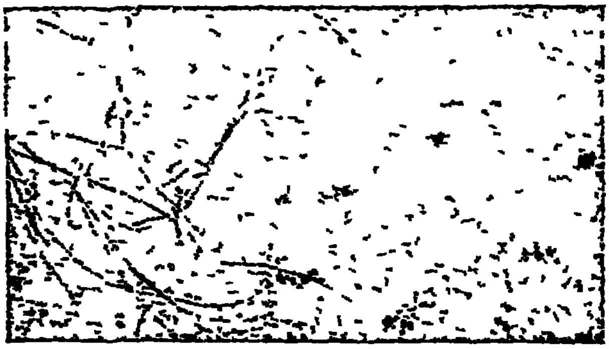


Fig 6—Case 5 petechial hæmorrhages in skin of thigh

The sexes are equally involved, and no age-group seems to be immune

The symptoms resolve as unoccluded venous channels dilate the intense congestion remits, and œdema fluid is slowly absorbed Often masses of small anastomotic veins become visible in the skin of the limb and lower abdomen, depending on the extent of the original occlusion

There is little difficulty in making a correct diagnosis when a clinical history or actual observation has indicated recurring thrombophlebitis Eventually as in case 3, one such episode by further occluding an already impaired venous system, is sufficient to cause tissue ischæmia with its sequelæ of pain and gangrene Further swelling and deep cyanosis are characteristic The area involved is usually well localised often to the end of the limb

It is however the single dramatic episode of massive thrombophlebitis which gives rise to difficulty, acute ischæmia of

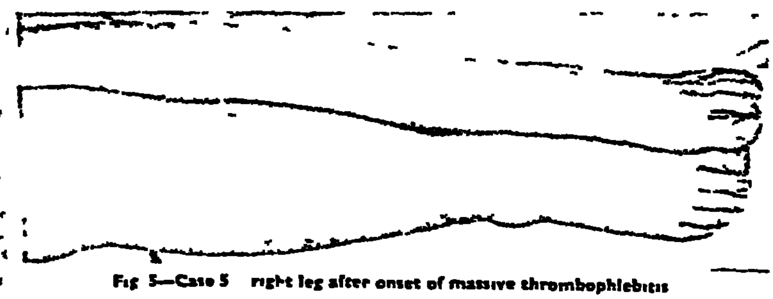

Fig 5—Case 5 right leg after onset of massive thrombophlebitis

DIFFERENTIAL DIAGNOSIS OF ARTERIAL OCCLUSION AND MASSIVE THROMBOPHLEBITIS IN THE LEG

	Arterial Occlusion	*Massive Thrombophlebitis*
1	Little, if any, shock	Severe shock may be present or incipient
2	Involvement of distal part of the limb even with proximal occlusion	Generally whole limb often with the lower abdomen, involved
3	Œdema absent initially and any late development is of minor degree	Œdema develops with dramatic rapidity and usually involves the whole limb
4	Waxy yellow colour or mottled cyanosis paling on elevation	Whole limb to groin dusky purple persisting on elevation
5	Subcutaneous veins poorly filled, “gutter” on elevation	Subcutaneous veins, turgid with blood, do not empty on elevation
6	No skin hæmorrhages	Petechial or more severe hæmorrhages
7	Subpapillary veins do not fill after pressure	Rapid refilling of subpapillary veins after pressure
8	No pulses and no oscillometric evidence of arterial pulsation present below occlusion.	Pulses may be absent Oscillations usually less than in normal limb
9	Pain usually not severe	Pain may be agonising
10	Any loss of movement is due to ischæmia	Any loss of movement is generally due to pain.
11	Hyperæsthesia, hypoæsthesia and anæsthesia may occur	Hyperæsthesia, hypoæsthesia, and anæsthesia may occur

arterial origin often being diagnosed in error (see table) It may therefore be helpful to describe the symptoms and signs of massive thrombophlebitis and later to compare them with those resulting from acute arterial occlusion.

The patient, while in bed or going about his normal activities, develops a severe pain in his leg, beginning in the upper thigh (Haimovici 1950) and rapidly extending downwards to reach agonising proportions within an hour Less often the pain begins in the region of the knee and spreads up and down Initially of an intense burning or paræsthetic nature, it prohibits either active or passive movement Almost coincidentally the limb takes on a dusky cyanotic appearance from the groin distally, petechial hæmorrhages may appear, and swelling begins, sometimes involving the lower abdominal wall As this congestion and œdema progress, compensation for loss of circulating blood volume may fail, with a rise of pulse-rate and fall of blood pressure, locally the skin appears tight and shiny with the changes of *peau d'orange*, and the superficial veins are distended The patient complains of a deep aching or bursting sensation in the limb

On examination the skin may be hyperæsthetic, hypoæsthetic, or patchily anæsthetic, especially in the most deeply cyanotic areas, it blanches only with the firmest pressure and rapidly congests again If subcutaneous veins can be massaged empty, it is only with difficulty—they may be thrombosed Skin-temperature is usually lowered, to a greater extent peripherally, and this is exaggerated by any associated circulatory collapse Raising the limb does not affect the colour or the degree of venous filling Deep muscular tenderness in the foot, calf, and thigh is usual, but for the first 24 hours tenderness over the major veins is rarely elicited, after that time, however, it becomes severe Initially, peripheral pulses may be felt even though they are relatively less than those of the opposite leg, later, œdema and any peripheral vascular collapse make their palpation very difficult Oscillometry usually indicates continued arterial pulsation

The rôle of associated arteriospasm in this condition is disputed Many (e g, Veal et al 1951, Turner 1952, Hershey and Snyder 1953) think that, if arterial spasm occurs—and it is recognised that it may occur reflexly in thrombophlebitis (Ochsner and DeBakey 19[illegible] —the part it plays in causing the symptoms is not cert[illegible] Others (Janes and Hopmans 1953, Martin 1953) re[illegible] arteriospasm as a sinister complication Con[illegible] Burch et al (1939) have shown experimentally that occlusion of the venous return from a limb can reduce oscillometric readings by more than half However, the absence of palpable peripheral pulses in massive thrombophlebitis may be due to previous atherosclerotic occlusive disease, the masking effect of œdema, or associated peripheral circulatory failure quite apart from spasm

Provided the threatened circulatory collapse is sur[illegible] or suitably treated, the dilatation of anastomotic vascular channels during the succeeding days leads to a [illegible] resolution of the œdema, blood flow improves, pain passes, cyanosis fades, petechial hæmorrhages are absorbed, and any resulting necrosis begins to demarcate. Massive gangrene is unusual, and part of the foot or [illegible] the toes may slough Though this sequence is typical, pain is by no means constant and may be absent (see case 5) So far as the development of gangrene is concerned, absence of pain seems to be a good prognostic omen Absence of pain, however, does not preclude the onset of severe, even fatal, circulatory collapse (case 5)

Immediately after the attack of massive thrombophlebitis, phlebitis of the opposite limb is quite possible (cases 1, 3, and 5), particularly when clot fills a common iliac vein There is also the risk of an occult phlebothrombotic process developing with subsequent pulmonary embolism From the small number of previously published cases this certainly seems to be rare

To summarise then, the clinical features of massive thrombophlebitis are those associated with a degree of vascular turgidity sufficient to arrest the circulation they usually overlie some other systemic disorder

Almost the contrary is true for the syndrome of acute arterial occlusion While embolism most commonly results from cardiac disease, and arterial thrombosis from severe atherosclerosis, the ischæmic limb in these conditions presents a picture of severe deprivation of blood Unless there is aortic thrombosis or a dissecting aneurysm (in which cases both legs will be involved) early pain is not a prominent feature, there is no severe shock, and life is not immediately endangered Even when the common iliac artery is occluded, it is rare for the whole limb to show ischæmic change as high as the inguinal ligament Thus, after occlusion of the external iliac artery, ischæmia reaches about mid thigh level, after occlusion of the superficial femoral artery it reaches to just below the knee-joint, and after occlusion of the popliteal artery it reaches to about the ankle joint This contrasts with the extensiveness of the fulminating attack of massive thrombophlebitis

Pain immediately after arterial obstruction is rarely severe and never has a bursting character, but paræsthesiæ and heaviness are not unusual Œdema does not develop immediately, and if it does occur in the “twilight” area of relative ischæmia it is slight As regards skin colour changes, there may be uniform cyanosis of the ischæmic part, a waxy yellow pallor, or a patchy mixture of the two colours, *slight pressure*, however, blanches the skin, which remains pale Petechial hæmorrhages do not occur Raising the limb produces or exaggerates the pallor and “gutters” the veins Areas of hypoæsthesia and anæsthesia are found, a [illegible] involving almost the whole of the ischæmic zone It may be easy to localise the site of arterial obstruction by simple palpation, otherwise oscillometry may be used The slight tenderness of a thrombosed artery developing one or two days after the occlusive episode is considerably less than that of the corresponding venous lesion Active or passive movement is rarely precluded by pain, but necrosis of muscle groups donetimes give rise to tenderness and contracture, rticularly in the calf Loss of movement of the toes d ankle joint rarely occurs from occlusion below the rel of the superficial femoral artery, and any gangrene sulting tends to be more extensive than that following ssive thrombophlebitis

The salient differences between the two conditions erefore lie in the extent of the changes, the colour of e skin, the type and severity of the pain, and the velopment of œdema with its risk of secondary circula- ry collapse Diagnosis should then be clinical, arterio aphy (Moore and Scott 1956) can hardly have a place hen the serious general condition of these patients is nsidered

The changes which develop in phlegmasia alba dolens iofemoral thrombophlebitis, white leg) are altogether ilder but may be precursors of the more extensive sease The upper limb has sometimes been involved y the process (Mills and Bennetts 1955), but not all ablished cases (Pringle 1938) attributed to massive rombophlebitis are altogether convincing, certainly is uncommon in this site

Moser et al (1954) state that gangrene develops in least half the limbs involved by massive thrombo- lebitis, and that a quarter of the patients die This tter figure seems one which should be capable of nsiderable reduction The most important aspect of eatment is the anticipation of circulatory collapse hole blood is lost from the circulatory volume into the mb, and what little escapes from it is hæmoconcentrated y the loss of much œdema fluid A large volume of line solution, plasma or plasma substitute, and blood likely to be required within the first 12 hours of the nset of the condition Delay can be fatal for the patient his, of course, applies to the fulminating attack, e staged development of massive thrombophlebitis, eing much more gradual, does not overtax the circula- ory system, and transfusion is not likely to be necessary

When general resuscitative treatment is under way, reatment of the limb can begin Perhaps the most ational measure is to remove as much clot as possible rom the femoral and iliac vessels This has been done uccessfully by DeBakey and Ochsner (1949), Miles 1951), and Ellis and Windham (1952), but Miles (1951) ttributed his success to associated ligation of the inferior ena cava, a manœuvre which has been reported to itiate the condition (Veal et al 1951) However, many atients with massive thrombophlebitis are in no condi ion for surgical intervention, the results of which are t best likely to be doubtful

The rôle of arteriospasm has been considered above Those who are impressed by the possibility of it advocate he use of sympathetic blocks, spinal anæsthesia, vaso ilators (Haimovici 1950, Halligan et al 1953, Janes and Hopmans 1953), and heavy sedation (Martin 1953) Others (Ebel et al 1952, Turner 1952), finding that none of these treatments affected pain, œdema or ischæmia, egard them as useless

Is it reasonable to induce vasodilation ? If the very doubtful entity of venospasm actually is a factor in the genesis of the condition (Manheimer and Levin 1954) its relaxation is obviously desirable To induce any arterial dilation, however, seems equally undesirable, there is already a surfeit of blood in the affected limb, and to increase this seems likely to make matters worse It is therefore suggested that the initial use of para vertebral blocks and vasodilators is illogical and should be avoided (Ebel et al 1952)

A further question which arises is the indication for anticoagulant therapy It has been pointed out that capillary pressure is not infrequently high enough to give rise to petechial hæmorrhages (DeBakey and Ochsner 1949, Veal et al 1951, Manheimer and Levin 1954) In the acute phase any increase of the clotting-time is obviously liable to worsen this tendency and possibly further to embarrass the circulation by increasing tissue tension In one case (not reported here) where anticoagulant therapy had been energetically pursued the entire skin area below the knee contained extravasated blood Since, therefore, anticoagulant therapy increases the liability to gangrene or its extension in the initial stages of massive thrombophlebitis it should not be used (Veal et al 1951) When, however, venous collaterals have begun to open up and symptoms subside, there may be a place for such therapy because the risk of further intravascular clotting in the same limb or else where remains Even so consideration will have to be given to the risk of hæmorrhage from any other associated pathology

It is obviously desirable to aid drainage of blood from the congested limb, and its elevation is certainly indicated Veal et al (1951) advocated vigorous exercise in an attempt to pump blood out of the limb This advice has been followed satisfactorily by Moser et al (1954) and was applied in case 5, when almost continuous active and passive movement of the leg was kept up for twelve hours This patient never gave any anxiety as to the leg becoming gangrenous, but it is felt that the exercise and vigorous intravenous therapy enabled him to recover from his peripheral circulatory collapse This régime initiated by Veal et al (1951) is therefore recommended in the treatment of massive thrombophlebitis, but in many cases it will have to be given after analgesics have been given to the patient The possibility that such treatment may give rise to pulmonary embolism has been raised (Mills and Bennetts 1955), but there seems to be little risk of this (*Lancet* 1955) The patient should be encouraged to move about in bed to reduce the risk of chest and other complications The heavy sedation which has been advised (Martin 1953) seems to have little to recommend it

Limbs incipiently gangrenous should be kept in an environmental temperature of 20°–25°C (68–77°F) because the tissue demand for oxygen will be reduced without the vasoconstriction due to cold resulting (Catchpole and Jepson 1955)

As soon as swelling has begun to subside and the patient's general condition is satisfactory, he may be allowed up with the limb well supported Although it has been noted (DeBakey and Ochsner 1949), and I have personally observed, that resolution may appear virtually complete, more commonly the typical indurated post-phlebitic leg results Gangrenous tissue should be allowed to separate and any precipitous amputation avoided because necrosis may be no more than skin deep

Whilst awaiting this development, the patient must be investigated to disclose any underlying disease which has predisposed to the attack of phlebitis

Summary

Five cases of massive thrombophlebitis (massive venous thrombosis phlegmasia cærulea dolens) are described

The rarity of the condition has undoubtedly been over-emphasised, with the result that it is often tardily diagnosed and inadequately treated

The pathology of the condition has been briefly outlined and the diagnosis and clinical course discussed

The urgent need for vigorous treatment early in the fulminating type of the disease to prevent or overcome shock and to avert a speedy death is emphasised

Attempts to induce vasodilation are contra indicated, and initial anticoagulant therapy should be avoided

Exercise is advocated to pump blood from the congested tissues, if it is not feasible to remove the offending blood-clot surgically

Any tissue necrosis which results should be treated with conservatism

I should like to thank Dr E G Rhind for permission to examine his patient and publish her case report (case 3) I am grateful to Prof R P Jepson for much encouragement in the study of this disease

INDUCTION OF LABOUR TO PREVENT RECURRENT STILLBIRTH DUE TO HÆMOLYTIC DISEASE

WILLIAM WALKER

SENIOR LECTURER IN OBSTETRICS, UNIVERSITY OF DURHAM

WHEN more than 95% of mature liveborn babies with hæmolytic disease can survive (Diamond et al 1950, Walker and Murray 1954) there is little indication for induction of labour before term unless it may prevent stillbirth The over all risk of stillbirth in hæmolytic disease is 15%, but varies from 2% following mild disease in the previous pregnancy to 80% following multiple stillbirths (Walker and Murray 1956)

With the cooperation of colleagues throughout the Newcastle region, we have in the past three years made a trial of premature induction in families with a high risk of stillbirth—i e, those in which a previous stillbirth has been due to hæmolytic disease and in which the father is homozygous D/D

Management

Clinical and radiological assessment was carried out at the 34th week of pregnancy If the fœtus was alive and not hydropic, labour was induced 35 days before the expected date of delivery During the first year of the trial induction was started by rupturing the hind waters with a Drew Smythe catheter, and, if labour did not begin within forty-eight hours, an intravenous oxytocin drip, as described by Theobald et al (1948), was given In the next two years an oxytocin drip for forty-eight hours was given, followed if necessary by rupture of the membranes If labour did not begin within forty eight hours, a second oxytocin drip was given In all cases where the membranes had been ruptured for more than forty eight hours, the patient received streptomycin 1 daily and sulphadimidine 1 g six hourly

TABLE I—RESULTS IN 108 CASES WITH PREVIOUS STILL

			Rh positive cases				
			No	Still births	Hæmolytic disease		
					Severe	Mild	
Not induced	Cause of previous stillbirth unknown		11	3 (31%)	7	4	1
	"Spontaneous"	Father heterozygous	13	9 (69%)	4	Nil	[illegible]
		Missed	6	5 (83%)	1	Nil	[illegible]
Induced			60	37 (62%)	23	Nil	[illegible]
Total			93				[illegible]

Using this induction routine, 21 babies were deliv per vaginam using Wrigley's forceps Another 4 ba were delivered by cæsarean section—1 because of fœ distress before the onset of labour, the others because failure to initiate delivery All 25 were delivered betw thirty five and twenty-five days before the expected da of delivery

Results

During the three years, 102 women were seen, early in pregnancy, who had previously had a stillbirth po attributable to hæmolytic disease 48, however, we not selected for induction—in 27 because the father wa heterozygous D/d, and in 15 because the stillbirth, after careful review of the history, was not regarded as due to hæmolytic disease 6 additional cases were not reco nised until admitted in labour The general result in all 108 cases are shown in table I

Where the previous stillbirth was not due to hæmoly disease the severity of the infant's illness was what w should expect in unselected material (Walker and Murra 1954), and only 1 of the 3 stillbirths was a case of hydrops fœtalis

The Rh-positive babies of heterozygous fathers sho the high proportion of stillbirths expected, and all th born alive were severely affected If we add to this gr the 6 Rh-positive babies detected too late for inducti the incidence of stillbirth in "spontaneous" ca 73% In the cases selected for induction, the incidence stillbirth is only a little less (62%), largely becau of the 37 stillbirths were at less than 35 weeks Howev only 3 of the 19 "spontaneous" cases (against 24 of t 60 "induced" cases) were preceded by more than 1 stillbirth due to hæmolytic disease, and, since multi stillbirths carry a worse prognosis, this would tend t make induction look less valuable than it is Table I

TABLE II—RESULT IN RELATION TO NUMBER OF PREVIO STILLBIRTHS AND STAGE OF GESTATION

Stage of gestation (weeks)	1 previous stillbirth		More than 1 previous stillbirth		Total	
	Still born	Live born	Still born	Live born	Still born	Li
Before 28	3		1		4	
28–32	3		7		10	
33–35	5		8		13	
36–37	5	17	2	6	7	[illegible]
After 37	2				2	
Total	18	17	18	6	36	[illegible]
Not recorded	1				1	
Total	36		24		60	

shows the duration and result of pregnancy in relation to the number of preceding stillbirths

We expected 30% of live births when there had been ne previous stillbirth, but we found 50% , when there ad been multiple stillbirths we expected 20% and found 5% The results were better in the first group, essentially because 68% reached 35 weeks' gestation, whereas in the second group only 35% did so The time of fœtal eath does not necessarily correspond with delivery, and re should mention that, though only 45% of the babies n the trial cases were stillborn by 35 weeks' gestation, 65% were already dead If, however, a pregnancy did reach 35 weeks satisfactorily, the prospect of bringing about a live birth was about the same whether there had been 1 stillbirth or more than 1—i e , 17 24 and 8 respectively

We have, therefore, without subdivision as to number of previous stillbirths, compared the "induced" and "spontaneous" cases which reached 35 weeks' gestation table III)

These findings are significantly in favour of premature induction (P=0 02—0 01), in spite of including 7 in the induced group, and only 3 in the spontaneous group, who were already dead or hydropic at 35 weeks If these cases are excluded a truer evaluation of premature induction can be made (table IV)

TABLE III—RESULTS IN PREGNANCIES REACHING 35 WEEKS' GESTATION

—	Live birth	Stillbirth	Total
Induced	23	9	32
Spontaneous	5	10	15
Total	28	19	47

This difference is highly significant and in favour of premature induction (P=0 004)

We conclude that if there has been a previous stillbirth due to hæmolytic disease, and a subsequent Rh-positive fœtus reaches 35 weeks' gestation, alive and not hydropic on X ray examination, premature induction at this stage gives a better chance of live birth than does spontaneous delivery

The prospect of live birth is high (probably more than 80%), but one must remember that the nearer a pregnancy approaches term successfully, the greater is the chance of spontaneous live birth Therefore the longer premature induction is delayed, the better will the results appear if early stillbirths are ignored

The importance of the Rh genotype of the father was recognised only late in the trial, and retrospectively it was seen that, of the three common genotypes homozygous for D, the prospect of reaching 35 weeks' gestation was poorer if the father was cDE/cDE (R_2R_2) (Murray 1956)

The Severity of Disease in "Induced" Liveborn Babies

Relatively severe disease is to be expected in any liveborn baby if a previous sibling was stillborn with hæmolytic disease In this series all the premature babies were severely affected and 5 out of 23 died In the figure we have shown the distribution of birth weight cord hæmoglobin, and bilirubin values

Birth weights varied from $3^1/_2$ to 7 lb , but 40% were between 5 and 6 lb and this distribution corresponds closely to the expected weight-distribution in babies of any parous women at $35^1/_2$ weeks' gestation (Walker, J 1955)

The average cord-hæmoglobin value was 68% (10 g per 100 ml) this should be compared with an average of 94% (14 g per 100 ml) for all cases of hæmolytic disease, in which only 48% have less than 100% (14 8 g per 100 ml) In 90% of the induced cases the level was below this

TABLE IV—RESULTS IN PREGNANCIES REACHING 35 WEEKS GESTATION WITH A LIVING AND NOT HYDROPIC FŒTUS

—	Live birth	Stillbirth	Total
Induced	23	2	25
Spontaneous	5	7	12
Total	28	9	37

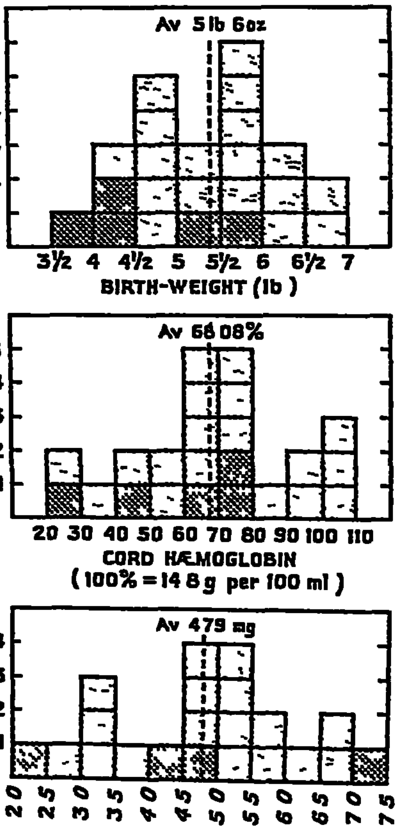
The cord bilirubin values also confirm the severity of the disease in the induced cases Of these nearly 50% had values higher than 5 mg per 100 ml , compared with 20% of the whole series

Treatment and Mortality

Babies were selected for treatment on the basis of cord hæmoglobin and bilirubin values, relying on the criteria we have used since 1951 (Walker 1953) All required early exchange transfusion, and were treated in the way already described (Walker and Neligan 1955) except that, in the light of early experience with "induced" babies, we decided to take into account the baby's cord-hæmoglobin value and were content with transfusion of smaller amounts—as little as 40 ml per lb in one or two very anæmic babies

We have taken as our criterion for repeating exchange transfusion a bilirubin level of 25 mg per 100 ml during the first 6 days of life 9 out of 18 survivors required multiple exchange transfusion compared to 13 (5%) of 255 other infants with hæmolytic disease who were treated by exchange transfusion during the same period None of the "spontaneous" group became so deeply jaundiced as to require repeated exchange transfusion There was no absolute correlation between the need for repeating exchange transfusion and birth-weight, cord hæmoglobin or bilirubin levels or the age at which the first exchange transfusion was performed

The other major difference between the "induced and "spontaneous" cases is in regard to mortality All 5 spontaneous liveborn babies survived, despite severe disease In contrast 5 of 23 "induced" babies died 4 died in the course of exchange transfusion—an event which is extremely rare, even in very severely affected babies, if they are born near term These deaths which are not fully explained took place without warning but after an appreciable amount of



Babies born alive after premature induction blood had been exchanged The baby, often well and improving since the start of transfusion, became cyanosed, the venous pressure was suddenly raised, respiration became gasping and irregular, the heart had already stopped, and resuscitation was impossible Necropsy supplied no direct explanation, though in all cases important contributory features associated with prematurity or premature induction were found—e g, 2 babies had severe pneumonia, and 3 had pronounced cardiomegaly, while tentorial tears, hyaline membranes, or pulmonary hypoplasia were present in some cases Recently in 2 cases not included in this report, labour was induced before term for obstetrical reasons Neither baby was very severely affected, yet both died during exchange transfusion

Discussion

Stillbirth remains the outstanding problem of hæmolytic disease The stillbirth rate in our material is 16%, which corresponds with other recent estimates (Davies et al 1953, Allen et al 1954), but the risk in a family is higher when there has been a previous stillbirth from this cause (Allen et al 1954, Walker and Murray 1956)

In considering a policy of induction before term, one must set the greater risk of neonatal death against the greater chance of live birth (Mollison and Walker 1952, Armitage and Mollison 1953, Allen et al. 1954) Kelsall and Vos (1955) recommended induction at 36 weeks' gestation for most cases of Rh isoimmunisation, but we do not think their figures justify the claim that nearly all stillbirths could thereby be prevented Dundon et al (1952) similarly estimated that there would be very few stillbirths if all babies alive at 36 weeks' gestation were delivered then, but other workers have been less optimistic Obviously the efficacy of induction depends on the time at which it is done and the time at which intra-uterine death occurs Davies et al (1953) held that induction at 35 weeks would prevent 75% of stillbirths, but Allen et al (1954) concluded that only 28% would be avoided by delivery at $36^1/_2$ weeks Our experience is more in line with this latter view, but in addition we have found that the chance of successfully reaching an advanced stage of gestation can be related to the family history We calculate that induction at 35 weeks can possibly prevent 50% of all hæmolytic stillbirths, but the proportion falls below 30% if hæmolytic disease has caused more than one previous stillbirth The stage of gestation reached in an earlier pregnancy is not an accurate guide to what may be expected in the present one, nor, in our experience, is it satisfactory to be guided by fœtal activity

On the evidence presented, we believe that premature induction is indicated in families where there has been a preceding stillbirth due to hæmolytic disease, and should be considered where there has been a previous "very severely affected" baby Induction at 35 weeks carries a good chance of initiating prompt delivery, and the degree of prematurity does not in itself carry a bad prognosis In families where two or more previous babies have been stillborn or very severely affected, one should consider delivery at 32 weeks—at which time elective cæsarean section will probably be indicated

If induction is performed because of a bad obstetrical history, severe disease in a premature baby must be expected and arrangements must be made for prompt (and in many cases repeated) exchange transfusion Some premature babies tolerate exchange transfusion badly, and we have found it expedient to do this in two stages, each taking half an hour with an interval of half to one hour between In deciding the volume of blood to be transfused we take account of the relative hæmoglobin values of baby and donor

Absolute rules cannot be laid down satisfactorily for the conduct of all cases.

Summary

Between July, 1952, and July, 1955, induction of labour at 35 weeks' gestation was considered in families in which a previous stillbirth had been attrib to hæmolytic disease

60 were selected for induction because the preced stillbirth was undoubtedly due to hæmolytic disea because the father was homozygous D/D

Only 25 of the 60 reached 35 weeks with a living fœt apparently normal on X-ray examination, all we induced at this stage

23 liveborn babies resulted, and, though all w severely affected by hæmolytic disease, 18 survived

Attention is drawn to the fact that many stillb from hæmolytic disease occur early in pregnanc that the premature baby with hæmolytic disease pre a difficult problem of treatment

Again we are indebted to our colleagues in obstetrics pæd trics and pathology throughout the Newcastle region and the staff of the Newcastle Maternity Units and National Bl Transfusion Service We thank especially Dr George And and Dr T D Davies for their help and interest

THE CORRELATION BETWEEN URINARY ŒSTROGEN AND VAGINAL CYTOLOGY

STRETTON YOUNG
M B St And

From the Clinicopathological Laboratories, Imperial Can Research Fund, Royal College of Surgeons of England

IT is very desirable that the treatment of metastati breast cancer by the administration of hormones or by ablation of endocrine organs should be controlled and rationalised by repeated assessment of the hormonal status of the patient For this purpose the first essential is to investigate the formation and utilisation of the œstrogenic steroid hormones, with the object of gaining knowledge of ovarian and adrenal cortical function In this connection it would be of inestimable value if it were possible to determine the œstrogen content of the circulating blood Until a reliable method applicable to the human cancer patient becomes available, we must be content with the chemical estimation of the œstrogens and their excretion products in the urine, together with a determination of the presence or absence of œstrogen stimulation of the secondary sex organs, judged by cytological examination of the vaginal fluid

A reasonably accurate biochemical method elaborated in the Medical Research Council's endocrinological unit in the University of Edinburgh (Brown 1955) measure the urinary output of œstrogens in three fraction— œstrone, œstradiol 17β, and œstriol The method is too elaborate and costly for routine clinical use, but its accuracy recommends it as a research method, and nce it has been standardised in a well equipped laboratory, many estimations can be undertaken by a trained technical staff

Unless supported by significant biological correlation, the chemical estimation of excreted œstrogens gives no precise information about the production and utilisation of œstrogens in the body We report here an attempt to determine the correlation between the level of œstrogens in the urine and the degree of œstrogen stimulation of the vaginal mucosa, as judged by vaginal cytology The observations were made in 53 premenopausal and postmenopausal women, whose ages ranged from 26 to 80 years the majority were postmenopausal, and some of them had mammary cancer

Methods

Vaginal Cytology

Vaginal fluid was taken from the posterior fornix, 75 specimens being obtained from the 53 women

Several methods have been proposed for recording the cellular pattern of the vaginal fluid Except in the technique proposed by Mack, a fixed film of the stained fluid is graded according to the intensity of the œstrogenic stimulation, judged by the predominant cell type The fluid from an unstimulated mucosa shows "deep" cells only, if the mucosa is moderately stimulated, "intermediate" cells predominate, and if it is powerfully stimulated most of the cells are "superficial" and many are cornified The grading may be assessed by simple inspection (Graham 1950) or by estimating glycogen-containing cells, for this purpose the glycogen may be stained by iodine vapour (Mack 1943) or by other methods such as Best's carmine after wet fixation in alcohol ether A differential count may be made, we have done this by counting 500 cells in each preparation, each group of 100 cells being taken from a different area of the film a chess-board graticule was used in one eyepiece and a measuring graticule in the other The frequency of five cell types was recorded

By the differential count three indices were calculated

(1) *Deep index* (percentage of deep cells)

(2) *Pyknotic index* (percentage of superficial cells, both cornified and uncornified)

(3) *Cornified index* (percentage of cornified superficial and intermediate)

Again by the differential count smears were assigned to the following groups or grades cited by Kasdon (1953)

Grade 0 —No œstrogen effect deep cells only.

Grade I —Very slight œstrogen effect, 25% deep cells with 75% intermediate cells

Grade II —Slight œstrogen effect, almost all cells intermediate

Grade III —Moderate œstrogen effect, 75% intermediate, superficial cells approaching 25%

Grade IV —Considerable œstrogen effect, 75% or more superficial

Our routine technique was to collect the vaginal specimen on the same day that a 24 hour specimen of urine was being obtained Several films of each vaginal fluid were prepared on slides immediately after collection These were appropriately fixed and stained, and the vaginal fluid from each patient was cytologically graded according to the following criteria

(1) Into one of five grades by simple inspection (Graham 1950)

(2) Into one of four grades from glycogen index by iodine staining (Mack 1943)

(3) Into one of four grades from glycogen index by carmine staining

(4) By differential cell count and calculation of deep index

(5) By differential cell count and calculation of the pyknotic index

(6) By differential cell count and calculation of the cornified index

(7) Into one of five grades from the differential count (Kasdon 1953)

Chemical Method

Œstrone, œstradiol-17β, and œstriol were estimated separately in 200-ml aliquots from the daily specimens of urine by the method of Brown (1955) The amounts of the three œstrogens excreted daily were calculated from the mean of the two estimations and the volume of the 24-hour urine In outline the method depends on the partial purification and separation of the three œstrogens and their colorimetric measurement, a spectrophotometric correction being applied for non-œstrogenic chromogens

Usually the smallest amount of each œstrogen calculated to be significantly different from zero is about 1 2 µg per 24 hours At this the lowest level of detection, there is an error of about ±50%—i e, if a result of 1 2 µg œstrone per 24 hours is obtained, the true figure may lie between, but not beyond, 0 6 and 1 8 µg per 24 hours The percentage error decreases rapidly as increasing amounts of œstrogen are measured, and at 2 5 µg per 24 hours of each œstrogen the error amounts to about ±20%

Values for the individual œstrogens in the 75 urine specimens taken were about equally divided between the ranges of 0–1 2 µg, 1 2–4 0 µg, and over 4 µg daily

Results

Correlation

Most of the films examined were random samples The remainder formed groups taken serially from each of three patients The large majority of the stained films prepared from 75 specimens of vaginal fluid were graded according to each of the seven cytological methods described For each of the resulting large number of graded films we had the corresponding 24-hour output of œstrogens on the day of collection of the specimen From these data the correlation coefficient (r) was calculated The number of comparisons made is indicated by n, and p is the probability

The results are seen in table I, which shows that

(1) The urinary output of œstriol correlates with grading by all methods of assessing œstrogenic stimulation of the vagina

(2) The total urinary output of œstrogen correlates with grading by all cytological methods except the glycogen index

TABLE I—RESULTS

Method of grading	Œstrogen excreted in urine (log µg in 24 hr)			
	Œstrone	Œstradiol	Œstriol	Total œstrogen

	10 38	9 116	1 784	0 547	21

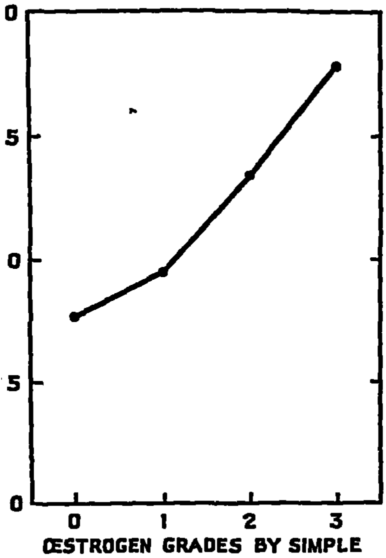
armine stained preparations and the deep index by ntial cell count

The output of œstrone correlates with grading by inspection and with the assignment of films into one of ades by a differential cell count

The output of œstradiol correlates with none of the methods used for the assessment of vaginal stimulation

The comparison between the output of œstriol and the nent of films to one of five grades by simple inspection it enumeration of cells gives the best correlation of any table

alculating r, instead of using the number of µg of estrogen excreted in 24 hours, we used the logarithm s figure because an almost linear relationship was to exist when the logarithms of these values were plotted against the degree of œstrogen stimulation determined by cytological grading



·Relation of means of log œstriol excretion s to œstrogen grades estimated by simple ction

In table II the arithmetic means of the outputs of œstriol and the arithmetic means of the logarithms of the outputs of œstriol are given against each of the œstrogen grades obtained by simple inspection The respective standard deviations are also given

neans derived from the log œstriol excretion figures otted against the œstrogen grade in fig 1 Although elationship is not exactly linear, the result is highly cant statistically

Estimations

results of serial estimations on specimens of urine erial vaginal films from a menopausal woman aged shown in fig 2 The pyknotic index follows the n shown by œstriol and the total output of œstrogen ugh not included in the graph, œstrone has a r correlation At low œstrogen levels the deep shows a clear inverse relationship to both œstrogens chemical and cytological methods show an initial ollowed by a gradual fall in both the urinary gen and the intensity of œstrogenic stimulation of ginal mucosa Œstradiol was excreted at a fairly nt rate 1 5 µg per 24 hours A particularly clear onship is present in this case between the pyknotic and output of œstriol, and maximum cornification place two days after the output of œstrogens was st

Two other short series also gave good correlation between vaginal cytology and urinary output of œstrogen

Accuracy of Œstrogen Estimations

Since the œstriol values show a high degree of correlation with the assessment of the vaginal reaction by all methods of grading, whereas the œstrone values correlate with the grade determined by one method only, the question arises whether this particular lack of correlation is due to inaccurate chemical estimation at very low levels of excretion Table III shows the percentage of estimations of urinary œstrogens grouped according to whether they fell below our lower limit of sensitivity or below that given by Brown (1955) Over two thirds of the estimations were below 4 0 µg per 24 hours

Nevertheless the œstrone and œstriol values have almost identical distributions The failure of œstrone to correlate cannot therefore be regarded as due to inaccurate estimations of very low amounts Œstradiol has a preponderance of low values, and this may explain the absence of any correlation

TABLE III—DISTRIBUTION OF ESTIMATIONS OF ŒSTROGENS

Percentage estimations	Œstrone	Œstradiol	Œstriol
From 0 0 to lower limit	27	48	26
From lower limit to 4 µg	42	42	43
More than 4 µg	31	10	31

Discussion

Some measure of agreement between the biological and chemical results was to be expected Brown (1956) has shown a close correspondence between physiological events and the output of œstrogen, while Rubenstein and Duncan (1941) have demonstrated correlation between vaginal cytology and urinary œstrogen measured by bio assay

Our work shows that there is a correlation between vaginal cytology and urinary output of œstrogen measured chemically, even when the latter is very low, and such a relationship implies that each method gives a result proportional to the amount of hormone or precursor in the circulation

The best correlation is that given by œstriol At first sight this is surprising in view of the alleged biological

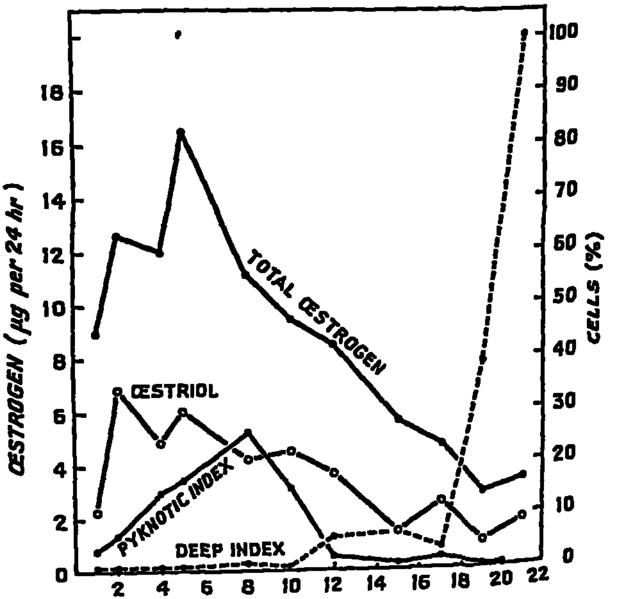


Fig 2—Serial estimations of urine and vaginal films from menopausal woman aged 56

inactivity of this steroid It may be that when œstradiol and œstrone act on their target organs they are metabolised to œstriol On this supposition the quantity of œstriol excreted would become proportional to the biological effect, and our results support such a thesis

Close correlation between the cytological and chemical findings is given by the œstrogen grading obtained by simple inspection and by differential counts At high œstrogen levels the pyknotic index, and at low œstrogen levels the deep index, both give good correlation The last three methods, however, require the performance of a differential count, which is unnecessary if the same result can be obtained without one

The value of the correlation appears to be statistical rather than practical In each œstrogen group the standard deviation is wide and there is considerable overlap in output of œstrogen from one group to another From the examination of vaginal fluid from different patients taken at random we do not think it possible to predict the urinary level of œstrogens with much accuracy We believe however, that in individual cases serial vaginal films can provide a good estimate of urinary œstrogen excretion , or, conversely, that urinary output of œstrogen is an accurate reflection of œstrogen effect on the patient

Summary

Vaginal cytology and urinary output of œstrogen have been compared on over 70 occasions, and a statistically good correlation has been found between them

We are indebted to Dr Clive Spicer for advice on the statistical methods used

PREGNANCY IN THE DIABETIC MOTHER WITH NEPHRITIS

T E Oppé
M B Lond , M R C P , D C H
LECTURER IN CHILD HEALTH IN THE UNIVERSITY OF BRISTOL

David Yi-Yung Hsia
M D
ASSOCIATE PROFESSOR OF PEDIATRICS,

PROFESSOR OF PÆDIATRICS,
BOSTON UNIVERSITY SCHOOL OF MEDICINE, MASSACHUSETTS

From the Department of Pædiatrics Harvard Medical School the Boston Lying in Hospital, and the Joslin Clinic, Boston, Massachusetts, U.S.A

The number of juvenile diabetics reaching the child-bearing years with already established renal complications is small, but probably diabetes lasting ten or more years becomes complicated by nephropathy in about 20% of cases (Forsythe and Payne 1956) Many such women wish to bear children and little is known about the outcome of pregnancy in these conditions Some clinics either discourage or terminate pregnancy, but no precise information has been published about the risk to the fœtus We have analysed a series of these cases and report our findings here

Material

In 1940-56 767 diabetic women attending the Joslin Clinic had pregnancies which attained viability (28 weeks) Of these, 31 (4%) were in White's (1949) class F, and 10 other women in class F became pregnant but had their pregnancies terminated naturally or artificially before 28 weeks Class-F pregnancies are uncommon, even in a clinic dealing with large numbers of diabetics A woman was classified as belonging to class F if, when her pregnancy became known, she had chronic renal disease in addition to diabetes The presence of other complications of diabetes—e g , calcified vessels and retinitis proliferans—were ignored for classification purposes All these women had diabetes of long duration, all had retention of nitrogen, and some had hypertension and diminished renal function Albuminuria was constant, but it is not uncommon in all diabetic pregnancies Many women had other vascular complications of diabetes Unfortunately the renal lesions of diabetes are not yet susceptible to precise clinical classification Moreover, although all these women probably had intercapillary glomerulosclerosis, it is uncertain how many had chronic pyelonephritis also

Methods

The pregnancies were managed according to the régime of Nelson et al (1953), which includes close supervision of diet and insulin requirements, together with early antenatal admission to hospital Some of the women also received large doses of sex hormones Hydramnios was almost constant, and most mothers had toxæmia in addition to the preceding renal disease Because of either this or diminished vitality of the fœtus delivery was by cæsarean section in all but 6 cases

One of the two pædiatricians (S S G and D Y-Y H) was present at each delivery and supervised personally the resuscitation and aftercare of the infant No matter what their birth-weight was, the infants were managed according to the routine practice for immature infants All were treated in incubators and given oxygen Fluids were withheld for the first forty-eight hours, and glucose was not given Respiratory distress was treated with oxygen and, in some cases, supersaturation of the atmosphere with water vapour Investigations and treatment were instituted when necessary for specific complications

Outcome of Pregnancy

Of the 41 class F mothers 15 were primigravidæ, 19 had had one previous pregnancy, and 7 were undergoing their third or later pregnancy Altogether the results of 83 pregnancies were known There were no maternal deaths, but therapeutic abortion was induced in 8 cases because of either increasing renal disease or advancing retinitis proliferans It was considered justifiable to sum the total pregnancy experience (table I) to give some idea of the over-all hazard to the fœtus, although we realise that, at the time of the previous pregnancies, not all the women had progressed to nephropathy or received the same obstetric care The 61% survival rate of the 31 viable fœtuses of the present series of pregnancies may be compared with the experience of 736 viable pregnancies in women with diabetes but without nephro-

TABLE I—OUTCOME OF PREGNANCIES

Outcome	Pregnancies		
	Present (41)	Past (42)	Total (83)
Miscarriage	2	26	28
Therapeutic abortion	8	0	8
Stillbirth	4	2	6 (8%)
Neonatal death	8	5	13 (16%)
Total loss	22 (54%)	33 (79%)	[illegible] (66%)
Survival of child			
Actual no	19	9	28
% of pregnancies	46	21	34
% of viable fœtuses	61	56	60

pathy who attended the same clinic and were managed in the same way (Gellis and Hsia, unpublished data)

Stillbirths	53 (7%)
Neonatal deaths	84 (11%)
Survivors	599 (82%)

The class-F pregnancies were associated with a greater mortality both from stillbirths and neonatal deaths, but there are insufficient data for us to draw conclusions about the abortion-rate The number of pre-viable fœtal deaths appears large in the class-F pregnancies, but without precise knowledge of the abortion-rate among other diabetic or non diabetic pregnancies it is impossible to speculate on the cause Some women appeared to have a tendency to repeated miscarriages, but such a history did not always preclude an eventually successful pregnancy

Intra-uterine Deaths

The intra-uterine deaths in the present series took place at 29, 31, 32, and 33 weeks, which fact suggests that the combination of diabetes and renal disease may prove lethal to the fœtus at an earlier stage than is usual in uncomplicated diabetes However, it was the practice of the clinic to forestall intra uterine death by early admission of the mother to hospital and rapid delivery at the first signs of diminished fœtal vitality This procedure may well have prevented intra uterine deaths at later gestational ages

Of the 27 live born infants 17 developed, in the neonatal period, respiratory distress characterised by tachypnœa and grunting respirations shortly after birth, followed by obstructive dyspnœa with retraction of the chest wall and attacks of cyanosis 8 of them died, and in 6 of these necropsy revealed hyaline membrane and resorption atelectasis These infants had been delivered by cæsarean section and died 1–96 hours after birth One other baby died 30 minutes after birth, having failed to establish effective pulmonary ventilation, necropsy revealed intra-uterine asphyxia and aspiration of cellular debris into the lungs The eighth neonatal death was ascribed to bronchopneumonia No important congenital abnormalities were observed

Birth weights

Many of these infants, unlike the characteristic infant of the diabetic mother, were small A comparison of birth-weights with those of 157 infants of diabetic mothers (classes A–E) by gestational age confirms this impression (table II)

TABLE II—BIRTH WEIGHTS OF INFANTS OF DIABETIC MOTHERS

Birth-weight (lb)	Gestational age (weeks)					
	< 33		33–35		35–37	
	Class F	Classes A–E	Class F	Classes A–E	Class F	Classes A–E
< 4	2	4	1	1	2	0
4–5	1	3	1	4	2	3
5–6	1	1	6	18	4	19
6–7	—	0	3	10	5	37
7–8	—	0	—	15	0	35
> 8	—	0	—	1	0	6

Discussion

The results of this study confirm the high fœtal mortality in pregnancy where maternal diabetes is complicated by nephritis (Pedersen and Brandstrup 1956) but does not indicate any special cause for this other than what might be suspected from the additive effects of the lesions That the intra-uterine environment is unfavourable is shown by the tendency to early intra-uterine death of the fœtus and by the latter's relatively small size After delivery the infant shows a tendency to hyaline membrane, which is known to be an almost constant feature of early neonatal death in the infants of diabetic mothers (Winter and Gellis 1954) Whether this susceptibility is a specific result of maternal diabetes or merely underlines the immaturity of these babies cannot be answered yet (Miller 1956)

The outcome of pregnancy reported here, unsatisfactory though it is, probably represents the maximum that can be achieved by the application of existing knowledge It therefore seems reasonable to offer the diabetic woman with nephritis an approximately 50% chance of bearing a surviving child under conditions of expert diabetic and obstetric management Such a risk may well be thought unjustifiable when the dangers of such pregnancies to the health of the mother are also considered

Summary

41 class F diabetic pregnancies are reviewed The fœtal wastage was 55%

The infants were smaller than infants of diabetic mothers usually are, but showed the same tendency to hyaline membrane as a cause of neonatal death

Our thanks are due to Dr Priscilla White for making available her records and to Dr Phillip Le Compte and Dr Kurt Benirschke for pathological material

NEPHROTIC SYNDROME

PREDNISONE THERAPY WITH TWO DEATHS FROM CELLULITIS

Ian P Ross
M D Lond, M R C P
MEDICAL REGISTRAR

John H Ross
M B Camb, M R C P
SENIOR MEDICAL REGISTRAR

THE LONDON HOSPITAL, LONDON

In some cases of the nephrotic syndrome treatment with corticotrophin or cortisone is of value (Roscoe 1956) The special risks entailed in this form of therapy have often been emphasised and are well summarised by Luetscher et al (1953) We record here two deaths, due to rapidly spreading cellulitis, during a trial of prednisone in the nephrotic syndrome

Case-reports

Case 1 —A man, aged 66 In February, 1956, an exacerbation of his chronic bronchitis and emphysema resulted in congestive heart failure, which was successfully treated with rest, digitalis, and mersalyl His urine was then repeatedly protein free The last weekly dose of mersalyl was given in April and acetazolamide (' Diamox ') was substituted

In August his legs swelled On examination he had moderate œdema, *normal* blood pressure, a daily urinary protein loss up to 28 5 g, plasma proteins 5 2 g per 100 ml (albumin 1 5 g, globulin 3 7 g), and blood urea 36 mg per 100 ml There were no signs of heart failure Renal biopsy showed changes compatible with early type II nephritis After 2½ weeks' rest with high protein low salt diet there was no improvement

Prednisone 20 mg b d for 6 days was then followed by 10 mg b d On the 7th day of this treatment, when there was still moderate œdema of the legs and back, the right lower part of the abdomen became hot, red, tender and œdematous This cellulitis rapidly spread over the abdomen back thighs legs, and chest The rectal temperature reached 101 5°F, and the patient s general condition rapidly deteriorated In spite of intramuscular penicillin 1 mega unit b d he died within 48 hours Necropsy was not performed

Case 2 —A man, aged 35, in February, 1956, developed œdema and was found to have heavy proteinuria and a low plasma protein level In June he had slight œdema, blood-pressure 150/100 mm Hg, a daily urinary protein loss up to 27 g plasma proteins 5 9 g per 100 ml (albumin 2 9 g, globulin 3 0 g), and blood urea 45 mg per 100 ml Renal biopsy showed changes compatible with early type II nephritis In spite of 3½ weeks' rest with a high-protein low salt diet the plasma protein had fallen to 4 7 g per 100 ml

Treatment with prednisone 20 mg b d was started on July 3 After 3 weeks the patient had a massive diuresis and improved, and the dosage of prednisone was reduced to 10 mg b d In September, on the same dosage, the œdema returned, proteinuria increased, and the plasma protein level fell to 4 3 g per 100 ml On Sept 8 the dosage of prednisone was reduced to 5 mg b d 2 weeks later when he still had moderate œdema up to the lower thoracic region, he developed pain in the back and pyrexia to 103°F, his lumbar region being hot, red, tender, and indurated This cellulitis rapidly spread over his back, abdomen, thighs, legs, chest and arms He was given corticotrophin 50 units instead of prednisone, intramuscular penicillin 1 mega unit b d and two days later aureomycin 250 mg q d s 2 days before death his plasma-sodium and plasma potassium levels were normal and his blood urea level 45 mg per 100 ml He deteriorated and died within 4 days of the onset of the cellulitis Immediate post-mortem culture of the subcutaneous fluid from the arms and leg grew *Escherichia coli*

Comments

The incidence and gravity of intercurrent infections in œdematous patients have been reduced by antibiotic therapy Both these patients were treated with prednisone and during treatment developed a spreading cellulitis which was rapidly fatal, the source of the infection is unknown Neither patient was grossly œdematous, and cellulitis would not normally have been considered a serious risk We think the fulminating nature of the infection was related to the use of prednisone, which is known to have an anti-inflammatory effect These two fatal cases have impressed on us the necessity for early recognition of cellulitis and for its immediate vigorous treatment

We wish to thank Sir Horace Evans for permission to publish

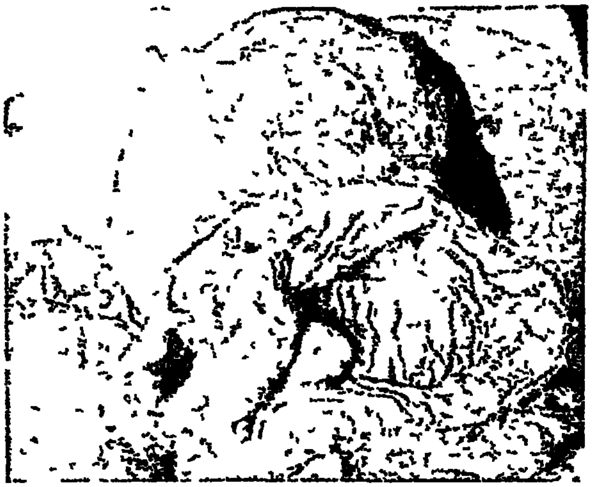
CONSULTANT SURGEON, LISTER AND NORTH HERTS HOSPITALS, HITCHIN

A MAN, aged 70, referred by Dr D Gullick, was admitted to hospital on Aug 30 1955, having had severe abdominal colicky pain for five days He had not vomited but he had lost his appetite and had had no bowel action since the onset of pain an enema given the previous day had been returned clear He had had no trouble with passing urine, there had been no increased frequency and no nocturia On admission he passed 10 oz of urine, which, except for a trace of albumin, was normal on routine examination Apart from attacks of bronchitis and an operation for varicose veins there was no previous history of importance In fact he had regarded himself as a fit man for his age

Examination —It was obvious that he was ill, for he was pale and sweating and his tongue was furred His abdomen was distended and tense and somewhat tender but there was no rebound tenderness Bowel sounds were scanty Hæmoglobin was 111%, and the blood urea level was 122 mg per 100 ml Straight radiographs of the abdomen showed coils of dilated gut suggesting obstruction It was difficult to be sure if there was free gas under the diaphragm



Giant diverticulum of urinary bladder lying posteriorly The bladder has been opened, showing the enlarged middle lobe of the prostate

Operation Findings —At laparotomy three hours after admission, gas escaped when the peritoneal cavity was opened, and a considerable amount of free purulent fluid was found An enormous cystic mass resembling a huge ovarian cyst was seen rising out of the pelvis Needle aspiration of this mass produced fluid like urine, and so a catheter was passed per urethram As urine was evacuated, the mass gradually subsided When 8½ pints of urine had been drawn off, a more or less normal bladder with a huge diverticulum was revealed

Further exploration showed a perforation of the first part of the duodenum This was closed by suture over a plug of omentum Purulent fluid was sucked out of the peritoneal cavity, and the abdomen was closed, a drainage tube being inserted The bladder was then opened by a separate suprapubic incision and an enlarged middle lobe of prostate was found acting as a ball valve obstruction of the internal meatus A De Pezzer catheter was inserted for drainage

Postoperative Course —During the next few days the patient was treated by gastric aspiration and intravenous drip, and his condition remained fairly satisfactory except that his urinary output fell very low (though it later improved) The ominous feature was that the blood urea (122 mg per 100 ml on admission) rose to 240 mg Ten days after the laparotomy (on Sept 9, 1955) the patient had a sudden hæmatemesis followed by melæna Despite blood transfusion he died next day

Necropsy Findings —The heart was a little dilated, and there were some degenerative changes in its muscle wall The lungs showed some basal congestion, but the remainder of the respiratory tract showed no abnormality The peritoneal cavity was dry except for a layer of thick pus around the spleen The stomach and intestines contained a considerable amount of blood and were dilated The hæmorrhage had come from two acute gastric ulcers There was a large duodenal ulcer, the perforation of which was noted to be firmly closed by sutures The liver showed pallor and fatty changes The spleen was engorged, the gall bladder and bile ducts were normal

The kidneys and ureters were normal, as were the pancreas and adrenal glands The bladder was hypertrophied (wall 1 cm thick), and its mucosa was congested showing patchy hæmorrhages The diverticulum on the posterior upper wall had an opening 3 cm in diameter and a capacity of about 3 litres The prostate showed slight uniform hyperplasia and a pedunculated middle lobe about 3 cm in diameter

Dr K A Mische photographed the specimen after stuffing the diverticulum with cotton waste Unfortunately, as it had been treated with solution of formaldehyde it had shrunk somewhat, and so the original huge distension seen at operation could not be fully reproduced Nevertheless the accompanying figure depicts the immense diverticulum along with the obstructing lobe of the prostate

Comments

The particular points of interest are -

(1) The absence of any previous history of disturbance of micturition (despite further postoperative questioning of the patient) and the fact that he passed urine in a normal quantity after admission to hospital

(2) The enormous size of the diverticulum It held nearly 8 pints at operation, and 5 pints post mortem after treatment with solution of formaldehyde Winsbury-White (1948), Ainsworth-Davis (1950), and Badenoch (1953) say that bladder diverticula may be larger than the bladder but do not suggest that any are nearly so large as the one reported here A search through the literature has not revealed any comparable case, but Pfau (1952) reported a diverticular calculus which weighed 610 g It fitted the diverticulum snugly, and radiologically this appeared to be nearly as large as a child's head, and so considerably smaller than the one described above

(3) Though theoretically it was probably unwise to remove so much urine rapidly, it was necessary to do so in order to gain access to the duodenal perforation

(4) Death was due to gastric ulceration and hæmorrhage and not, apparently, to uræmia (though this no doubt was a factor), because necropsy revealed normal kidneys

Reviews of Books

Pulmonary Emphysema

Editors ALVAN L BARACH, M D, clinical professor of medicine, Columbia University College of Physicians and Surgeons, HYLAN A BICKERMAN, M D, assistant clinical professor of medicine, Columbia University College of Physicians and Surgeons Baltimore Williams & Wilkins London Baillière, Tindall, & Cox 1956 Pp 545 80*s*

THIS book will be welcomed by those who are looking for a comprehensive, authoritative account of pulmonary emphysema

Different aspects of the subject are discussed by eighteen well known American experts In the opening chapters Barach, Bickerman, and G J Beck discuss methods of therapy employed at New York Presbyterian Hospital In later sections there are interesting appraisals of fairly new forms of treatment—continuous and intermittent positive pressure breathing, bronchial exsufflation, steroid therapy, and graduated exercise in an oxygen enriched atmosphere—but the most valuable feature of the book is the insistence on examining problems in the light of fundamental work on respiratory physiology The disturbance of pulmonary function in emphysema, and its effect on blood gas exchange and on the pulmonary circulation, are analysed in detail, and there is a chapter on lung function tests of value in clinical practice It is unfortunate that in so useful a book the writing does not always match the material some contributions could be described as treatises on the shortwinded by the longwinded

The Microscopic Diagnosis of Human Malaria

Part II *A Morphological Study of the Erythrocytic Parasites* JOHN W FIELD, C M G, M D, director, Institute for Medical Research, Federation of Malaya, P G SHUTE, M B E, assistant director, Malaria Reference Laboratory, Medical Research Council Kuala Lumpur Government Press 1936 Pp 251

THIS is the sequel to an earlier volume, *A Short Descriptive Atlas of Thick-Film Diagnosis*, published in 1918

The present volume begins with a short history of the microscopic diagnosis of malaria in man, and goes on to describe the parasites and their relations with the host red cells The terms applied to the various stages of the parasites are defined and the changes which take place in the cells are described The question whether the parasites are in or on the cells is left undecided

There are separate chapters for *Plasmodium falciparum*, *P vivax P malariæ*, and *P ovale*, and the authors have adopted a uniform scheme (with appropriate variations) for them all, though *P falciparum* receives most space These chapters contain much more than observations on microscopic diagnosis, and the book is, in fact, full of valuable information not always easy to find elsewhere, on a very wide range of subjects connected with the parasites and even the diseases they cause The pre erythrocytic and exo erythrocytic stages are referred to, but are not described at length since they do not come within the scope of the book

Methods of examination for malaria parasites—during life and after death—are dealt with, and technical details are given in a full chapter, but perhaps the most notable feature of the book is the extensive set of 59 full page plates, 24 in colour and the rest in monochrome, illustrating parasites at all stages as seen in thin and thick blood films The illustrations of the Malayan parasites are all new, being made by Yap Loy Fong at the microscope in the course of day to day work They are beautiful The hundreds of monochrome drawings depict the parasites in, one would say, all the shapes they could assume There are also coloured plates of spores, pollen grains, and other cells of vegetable origin, and other objects which might confuse a diagnosis

This book is a masterpiece which should be available in all laboratories in which the diagnosis of malaria is undertaken, and in all institutions where the subject is taught

Diagnostic différentiel radiologique des ulcerations gastriques

GEORGES CANDARDJIS Paris Masson 1956 Pp 188 Fr 1500

THIS book is based on an analysis of clinical records and radiographic examinations of some 133 patients submitted to gastrectomy between January, 1950, and December, 1954 The radiological signs are described, and the value of each is discussed in detail It is a comprehensive and good review of a difficult subject

Progress Report on Birth Control

LELLA SECOR FLORENCE, chairman of the Birmingham Family Planning Association London Heinemann Medical Books 1956 Pp 260 21*s*

THE title of this book might lead readers to expect a complacent account of grateful patients attending at expanding family-planning clinics Instead it recognises frankly that there is still much progress to be desired

The book deals mainly with a survey carried out by the Birmingham Family Planning Association on patients attending their clinic during 1948, with a careful follow up of a large number (about half) who failed to return This survey disclosed that to many couples methods of contraception advised at clinics are far from fully acceptable or reliable, and the author urges the need for examination, not only of the work of clinics, but of the general approach of the medical profession to this urgent problem Sterilisation and therapeutic abortion are discussed with forthright courage

All workers, medical and lay, in family-planning clinics should read this book, but it will also be useful to other doctors, nurses, and social workers

---

Sequeira's Diseases of the Skin (6th ed London J & A Churchill 1957 Pp 843 £3 5*s*)—The new edition of this book, appearing ten years after the last, is most welcome The editors, Dr J T Ingram and Dr R T Brain, have ensured that it remains well written, balanced, and comprehensive without being tiresomely encyclopædic Theory and practice are equally well represented, and bibliography is limited to a helpful minimum Omission of some of the reproductions of drawings might dispel the slight aroma of mothballs that may unreasonably discourage the use of a book which otherwise has an up to date freshness

International Review of Cytology (Vol V New York and London Academic Books 1956 Pp 570 92*s*)—The latest issue of this well established annual series, edited by G H Bourne and J F Danielli, includes a comprehensive and magnificently illustrated survey of the achievements of electron microscopy, written by F S Sjostrand of Stockholm Other articles cover such subjects as enzymic adaptation, the subcellular organelles of muscle, and the measurement of intracellular pH, while medical readers may be particularly attracted by T A J Prankerd's paper on transport across the erythrocyte membrane and A H Coons's review of the histochemical applications of labelled antibodies

THE LANCET
LONDON SATURDAY, FEB 16, 1957

Clinical Picture of Sickle-cell Disease

The sickle cell diseases have been the subject of intensive research ever since the demonstration by Pauling and by Perutz that the extraordinary shapes seen in the red blood-cells were due to the presence of an abnormal type of hæmoglobin which showed curious biophysical changes when exposed to relatively low concentrations of oxygen Harris and his colleagues,[1] in a recent survey, summarise the biophysical change as follows ' in hæmoglobin solutions of concentrations comparable to intracellular conditions, the abnormal hæmoglobin S molecules undergo alignment and parallel aggregation following deoxygenation to form birefringent hæmoglobin tactoids Consequently, the conclusion was reached that in all probability the birefringent sickled cell is a membrane covered hæmoglobin tactoid " (A tactoid is a spindle-shaped liquid crystal mass) We now know that in sickle-cell anæmia the red cells contain 75–100% of this unusual hæmoglobin (hæmoglobin S), with 0–25% of the normal hæmoglobin A In the sickle cell trait the red-cell hæmoglobin is a mixture of 25–45% hæmoglobin S with 55–75% hæmoglobin A Three other sickle cell diseases have been identified in sickle-cell/hæmoglobin-C disease the proportions are about 50% hæmoglobin S and 50% hæmoglobin C , in sickle-cell/thalassæmia disease, 67–82% of the hæmoglobin is the sickle cell form and up to 20% is fœtal hæmoglobin, the small remainder being hæmoglobin A , the third form (sickle cell/hæmoglobin-D disease) is so far less well-known (a case was described in our columns by Stewart and MacIver[2]) In all these varieties the oxygen tension at which tactoid formation and sickling can be induced is roughly correlated with the proportion of hæmoglobin S in the red cells of a particular patient

But patients with sickle-cell anæmia vary considerably in the clinical severity of their disease They can carry on for long periods in a precarious state of equilibrium between mild hæmolysis and red-cell regeneration, and then suddenly a hæmolytic crisis causes severe anæmia and grave illness People with sickle-cell trait or with the other varieties of sickle cell disease rarely suffer any disability and their abnormality is discovered only if their blood is examined because they have some illness, or because a relative has sickle cell anæmia But instances have lately been recorded of people who suffered a splenic infarction during an aeroplane flight, and who were found to have sickle cell trait or one of the other related conditions Rotter and his colleagues[3] described 6 such incidents in 3 the patients had sickle cell trait, in 2 they had sickle-cell hæmoglobin-C disease, and the sixth had sickle-cell thalassæmia , 5 were American Negroes and 1 was a Puerto Rican Griggs and Harris[4] studied the levels of oxygen tension at which the bio physical changes of sickling appeared in the various syndromes in sickle-cell disease, sickling will occur at an oxygen partial pressure of 60 mm Hg, a tension corresponding to that of mixed venous blood , the patients with 50–80% of hæmoglobin S, such as is found in sickle-cell/hæmoglobin-C and sickle-cell/thalassæmia diseases, must have a lower oxygen tension of about 40 mm before sickling appears , and in sickle-cell trait the oxygen partial pressure must be reduced below physiological levels (to 10 mm) before the cells will sickle Even though the patients who had splenic infarction were travelling in unpressurised planes, it is not certain that the oxygen partial pressure in their mixed venous blood fell as low as 10 mm , and it is noteworthy that symptoms did not come on until the patient had been some time in the air All this suggests that some factor in addition to low oxygen tension is concerned in the production of the *clinical* manifestations of the sickle-cell diseases Allison[5] suggests that this additional factor is time—the time of exposure of abnormal red cells to low oxygen tension -

What Allison has done is to repeat some older experiments in which blood from patients with sickle-cell disease is equilibrated with gas mixtures under conditions corresponding to mixed venous blood , such a gas mixture has an oxygen partial pressure of 40–45 mm , and when blood from a patient with sickle-cell disease is equilibrated at 37°C for four hours 10–20% of the red cells become sickled But if venous blood from an antecubital vein of such a patient is fixed by formalin immediately after withdrawal, sickle cells number less than 2% The reason for this is that a period of some *minutes'* exposure to low oxygen tension must elapse before the maximum sickling develops , thus, Allison shows that after two minutes' partial deoxygenation the proportion of sickled red cells is about 5% but after six minutes it has risen, in various samples, to between 12% and 18%, most of the increase taking place between two and four minutes From estimations of circulation-time, it seems likely that under physiological conditions most red cells are deoxygenated for ten to twelve seconds, and only a few for longer than fifteen seconds Thus, though most tissues are sufficiently low in oxygen to induce some sickling of red cells in persons with sickle cell disease, the fact that the red cells are exposed for only fifteen seconds or so means that most cells will be re-oxygenated before they can become sickled But if anything holds up the flow of cells through the tissues, the proportion of sickled cells will rise rapidly , any form of vasoconstriction or inflammation for example, could in that way increase sickling, and since the sickled cells themselves are likely to intensify the hold-up by blocking blood-vessels, it is easy to see how a " crisis " can be built up Allison observes that restoration of sickled cells by re-oxygenation takes just as long as the process of sickling, so that when sickled cells escape into the general circulation they will not stay long enough in well oxygenated parts to allow them to revert to a discoid shape As Harris et al[1] point out sickled cells are mechanically fragile and rapidly destroyed so that once sickling begins on any sizeable scale, a hæmolytic phase soon appears Allison also notes that sickling takes place more readily in the spleen than in other organs, and in the spleen stasis of blood is physiological

[5] Allison A C *Clin Sci* 1956, 15, 497

As we have already seen, in patients with sickle cell variants, sickling occurs only when the oxygen tension is reduced to between 15 and 40 mm , and in people with sickle-cell trait, oxygen pressure must be even lower The only conditions in which such low pressures are commonly found are in aeroplanes ROTTER et al[3] think that persons with sickle-cell trait may be in danger of sickling and splenic infarction only when flying at 10,000–15,000 feet in unpressurised aircraft , but persons with sickle-cell/hæmoglobin-C or sickle-cell/thalassæmia disease may have sufficient abnormal hæmoglobin for sickling to develop at 4000–6000 feet, and many commercial airlines operate at such heights They think the problem sufficiently important to warrant the screening, by paper electrophoresis, of Negro and Puerto Rican military personnel to detect those who have any abnormal hæmoglobin Sickle-cell diseases are also common in the West Indies (HERRICK's original case, described in 1910, was a West Indian from Grenada), so the same problem may arise there In fact, the diseases produced by abnormal hæmoglobins may become of increasing significance in many ways because they are common in countries where much has lately been done to check malnutrition and the infectious diseases, which were prolific causes of death and which made the hæmoglobin disorders seem relatively trivial LEHMANN[6] remarks how the hæmoglobin abnormalities may thus assume increasing importance in many parts of the world , the change is already apparent, he points out, in the Lake Kopias area of Greece, where sickling and thalassæmia are common but where the once formidable malaria has been eradicated, and where the hæmoglobinopathies are now the most pressing medical problem

Keratinous Cysts in the C.N.S

KERATINISING squamous epithelium in the wrong place behaves with great uniformity, wherever that place may be (and most parts of the body may be involved) and by whatever mechanism of displacement, maldevelopment, metaplasia, or even benign neoplasia it may get there It rounds off into a cyst, and the gradual accumulation of keratin leads to the growth of the cyst, a growth measured often in decades rather than years Breakdown of the keratin results in the accumulation of that ultimate indigestible fragment of most protein complexes, cholesterol The cyst contents are in fact highly irritating and excite a violent granulomatous reaction if the protecting layer of squamous epithelium breaks down In the body generally it is easy to recognise this constant pattern in "sebaceous" cysts, in implantation dermoids, in the cysts which complicate buried whole-skin grafts and the healing of epithelialised sinuses, in ureteric stumps, in line-of-closure dermoids (of which branchial cyst is the type), and in benign teratomatous cysts like the ovarian dermoid The presence of sebaceous glands and hair follicles in the lining of the teratomatous cysts (and sometimes in the line-of-closure dermoids, and rarely in the other types) makes remarkably little difference to the behaviour of these cysts, though it alters the appearance of the contents For this reason, little care has been taken to distinguish in ordinary speech between the terms "dermoid" and "epidermoid" cysts

Keratinous cysts in and about the central nervous system are usually described (often under the name of "pearly tumours") as though they were a separate entity, and had an element of unexpectedness denied to similar cysts elsewhere In fact they differ little in diversity of origin and uniformity of behaviour from those found elsewhere in the body They are not very rare, forming as much as 1% of reported series of cerebral "tumours" Series as large as 23 cases[1] have been described in the past, and TYTUS and PENNYBACKER,[2] in Oxford, have lately recorded 43 cases Their work illustrates the many different sites in which these lesions may arise 2 were pericranial, 6 orbital, 6 petrous, 2 diploic, 2 suprasellar, 7 intracerebral, 3 cerebello-pontine, 8 midline subtentorial, and 7 spinal A few of these can be extracted as special groups 3 of the midline subtentorial and 2 of the spinal cysts had associated dermal sinuses, which could clearly be responsible for the complication of septic meningitis , and, perhaps for that reason, this variety often causes symptoms early in life These midline cysts are obviously due to imperfect closure of the neural canal, a simple and obvious type of congenital lesion The suprasellar ones are perhaps related to Rathke cysts The petrous lesions include some at least of the "cholesteatomas" of the otologists it is interesting to find that it is by no means certain that these are the chronic infective granulomas that they are generally assumed to be, but may be primary keratinous cysts of the petrous bone infected secondarily from the middle ear Teratomatous cysts of the pineal body or elsewhere in the median plane must also be included, though they are rare and usually malignant[3] Benign forms do occur, however, and it is not clear whether TYTUS and PENNYBACKER saw no such lesions or have deliberately excluded them The remaining cysts seem to be scattered almost at random through the brain, the meninges, and the adjoining bone They are not confined to the midline, and malocclusions of the neural canal will not account for them It can only be supposed that, since the brain is ectodermal in origin, and the meninges and a surprisingly large part of the cranium arise from the neural crest[4] which is also ectodermal, we are witnessing the occasional anomalous appearance (presumably congenital) of the most characteristic end-product of the ectoderm, squamous epithelium, at these unlikely sites

The symptoms to which these cysts give rise are those of any benign space occupying lesion of very slow growth The absence of protein changes in the cerebrospinal fluid may be of help in diagnosis Treatment should clearly be excision as early as possible Even when involvement of vital structures makes complete excision of the lining epithelium impossible, the slow rate of growth fully justifies partial removal , but escape of the irritant contents into the C S F is a complication to be avoided if possible

[4] Hörstadius S The Neural Crest Oxford 1950 chapter 3.

The analogy between these cysts and those appearing elsewhere in the body has recently been completed by CHOREMIS et al,[5] who demonstrated that implantation dermoids can arise in the spinal canal, and described 6 examples after recovery from tuberculous meningitis CHOREMIS et al justifiably assumed that these cysts arose from squamous epithelium carried into the canal during one of the many spinal punctures involved in the treatment of tuberculous meningitis It is curious that this sequel has not been observed before, for examination of drill biopsies shows how often an ordinary needle carries a little disc of skin in with it CHOREMIS et al used a spinal needle without a stilette, and it may well be that the general use of a stiletted needle for spinal puncture has had the unforeseen but fortunate result of preventing this unpleasant complication

"Doctor"

IF names are important—and they are—the descriptions and titles given to different kinds of doctor in this country should be reconsidered before they become any more chaotic In the first place, is it allowable to use the word "doctor," in this way, to denote members of our own profession, implicitly excluding anyone without a medical qualification? In his article a fortnight ago Dr GEORGE GRAHAM explained how last century the holders of medical licences managed to capture for themselves a title which, in its primary meaning, belonged only to holders of university doctorates Whether or not this act of aggression was justifiable, it has certainly been successful—so successful that the secondary meaning of the word is now dominant, and when people say 'He s a doctor" or "Is there a doctor in the house?' there is no thought in their minds of higher degrees or of any faculty but medicine Of course everybody knows that there are other kinds of doctor—in law, divinity, science, music, philosophy, and so on—but the assumption is that anyone called Doctor is medical unless stated to be otherwise In any medical context or environment there is particular reason to suppose that the title has a medical connotation and this week we publish a letter showing how much difficulty and annoyance can arise, in consequence, where doctors whose degrees are not medical are associated with our profession in their work In this journal, to prevent any misunderstanding, we have long made a practice of referring to non medical doctors on their first mention as "Miss A B Dash, PH D, or "Mr A B Blank, D SC"—after which explanation we naturally accord them their proper title To many this has seemed tiresome and invidious, but it is at least better than the custom by which some hospital nurses and others refuse to call anyone Doctor unless he is on the Medical Register No doubt, as the Medical Act of 1858 says "it is expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners', but it is paradoxical, to say the least, that titles which are incontestable because conferred by a university, should thus be set aside in favour of one which is conferred only by courtesy and custom Now that some of the best work in medicine is done by science graduates who do not happen to have a medical qualification, most hospital workers should surely have become accustomed to the presence of more than one kind of doctor in the Greater Medical Profession[1], and politeness if nothing more suggests that doctors of science or philosophy should be addressed in hospital as they would be outside Has not the time come, indeed, when our emphasis could be less on distinctions and more on the common effort?

The next anomaly is that, though our entire profession have acquired a *de facto* right to call themselves Doctor, this title is spurned by many of those who hold it *de jure* as university doctors of medicine If we ask why surgeons should have cherished their lesser title of Mister, and why obstetricians and gynæcologists adopted it, the answer may be that they liked the prestige of difference, or that they loved tradition, or merely that the public were known to associate Misters with rather higher fees These reasons may be respected, or at any rate understood but is it really still necessary or desirable to lay so much stress on the unlikeness of the surgeon to other doctors? Times have changed since WOODALL in 1639 could epitomise the characteristics of the two branches of the profession by saying that "the more learned sort are justly stiled by the title of Physicians, and the more experienced sort are called Chirurgions or Surgeons"[2] Today not only are surgeons learned and physicians experienced, but the former sharp division between their functions is breaking down With physicians using operative techniques, and surgeons practising electrolytic augury, the everyday work of many specialties shows an increasing reintegration of medicine and surgery, and we are already seeing the emergence of neurologists and thoracologists who are professionally ambidextrous—limited, perhaps, by the region or system with which they are concerned, but paying no attention to the limits formerly denoted by "surgical" and "medical" For our part we deplore the persisting separation of surgeons, not only because it discourages a natural evolution in the specialties but also because it is bad for the profession The functional union which was officially achieved in 1858 with the creation of a Medical Register has never been completed except on paper, but it would be brought a stage nearer reality if surgeons and gynæcologists would hearken to the words of Dr GRAHAM, and of Dr LAMBERT ROGERS last week—if they would curb their separatist tendencies, and accept the same honourable title as all the other exponents of our science and art

If specialists in surgery are to be asked to sacrifice, for the general good, their title of Mister, specialists in medicine may equally be asked to abandon their lien on the designation of physician, which ought to be once more at the disposal of any member of the profession In the old days the family doctor put on his plate Physician and Surgeon, and only comparatively recently has the idea arisen that these names are the exclusive property of consultants *who confine* themselves to one or other of the branches If the fellows or members of the Royal Colleges of Physicians react to our suggestion by claiming a *monopoly* we shall remind them of Henry VIII's remarks

[5] Choremis C Economos D Papadatos C Gargoulas A *Lancet* 1956 ii 437

[1] See *Lancet* 1956 ii 779

[2] See New English Dictionary, vol vii p 807

> “ Forasmuche as the science of phisicke dothe comprehend the knowledge of surgery as a speciall membre and parte of the same, therefore be it enacted that anny of the said company or felawshipp of Phisitions may exercise the said science of Phisick in all and every his membres and partes ” [2]

The practice of surgery, then, does not prevent a person being a physician—a principle indeed inherent in the present constitution of the London college, which since Lord DAWSON’s time has conferred its fellowship on people in almost every department of medicine, including a number who are known elsewhere as surgeons. If “ physician ” could be restored as applicable to anyone with a medical qualification, ‘ family physician,” or even “ general physician,” could take the place of “ general practitioner ”—a term without ancestry or international currency, conceived (we believe) in desperation and a Government office. It could be used, too, in describing any post held by a doctor as such—e g , physician biochemist to St. A’s Hospital, or physician administrator to St. B’s.

Which brings us to a neologism that really does matter—“ medical officer ”. To many people, of course, this seems no more than a harmless synonym for doctor ; but that is either because they are insensitive to its implications or because they are no longer interested in professional freedom. In its military sense, “ officer ” implies a person occupying some position in a chain of command ; and in clinical medicine there should be no chain of command. In administration, “ officer ” means a person holding office under government ; and in this sense it is wholly inapplicable to hospital doctors or general practitioners in the National Health Service, who work under contract with a non-governmental board or committee and are definitely not Civil Servants. As everybody well knows, patients attending a hospital or surgery want the help of a doctor, not of an official ; and it would be salutary to emphasise the correct personal relationship of doctors with their patients by eradicating from medicine all use of the bureaucratic term ‘ officer ”. The professional equivalent is “ physician ” or “ surgeon ” ; and in hospital the present casualty officers and resident medical officers could properly be called casualty house surgeons (or assistant casualty surgeons) *and resident assistant physicians*. In industry there is the same need for the doctor not to let himself be represented as an official ; and, instead of industrial medical officer, he should be called industrial physician. For the M O H and his staff ‘ medical officer ” is partly accurate ; for, besides advising his authority, the M O H is an executive officer, charged with enforcing the law ; but, even so, it is preferable to think of him primarily as physician (or health physician) to his borough or county. Again, in the Civil Service, though technically doctors are officers of the Crown, they exert their influence almost entirely as advisers, and it would be better if SIR JOHN CHARLES were *called chief physician to his* Ministries. Our terminology should be such as to show that, wherever a doctor is working, he is there as a member of his profession ; and, *in* small things as *in* great, we should use the names and words that belong to our profession rather than those that belong to government. Thus for doctors to say (as so many now do) that they are going “ on leave ” is in 1957 no longer excusable as a nostalgic echo of the war. In the N H S at any rate, the doctor is not a subordinate who applies for leave but a physician who takes a holiday or vacation when he is satisfied that his patients’ needs can be temporarily met by someone else. Too many members of our profession have shown themselves readily addictable to bureaucratic language, and this addiction is more perilous than anything that administrators could do to the profession from outside. If doctors continue long enough to think of themselves as no more than medical officers in what so many of them persistently miscall a State service, *that is what they will infallibly become*. For as a man “ thinketh in his heart, so is he ”.

Annotations

TRAINING THE ASSISTANT

IN 1954 the General Medical Services Committee of the British Medical Association appointed a subcommittee to examine the scheme for training assistants in general practice. Their report [1] is a clear endorsement of the scheme, which has fully justified itself and should remain a permanent feature of the National Health Service. The report makes constructive suggestions which would increase the value of the scheme still further, and it proposes that an advisory body be set up. This body would keep the future evolution of the scheme under review, and it would include two members of the council of the College of General Practitioners. This collaboration with the college at the centre might be extended to the periphery, and the selection boards of local medical committees, who interview applicants for appointment as teachers, might well seek the help of the postgraduate education committee of the college faculty.

The trainee assistants scheme could usefully be expanded as more family doctors prove that they can teach others to attain the high standards of work they have themselves achieved. *The selection of teachers* must be strict, but the proposed advisory body would have promising material to develop ; and teachers, potential and actual, would be encouraged to attend courses, such as those offered by the British Postgraduate Medical Federation.

Perhaps the most important line of future development is indicated by the report’s remark that the advantages of the scheme should not necessarily be restricted to those intending to make a permanent career in general practice. Although the present arrangements were devised for general practitioners, a number of registrars take advantage of a year’s training in general practice. A full year’s work with a general practitioner might restore to the future consultant something which he is in danger of losing—the ability to see beyond the limits of an ever narrowing specialty. Some senior hospital appointments are now being filled by doctors whose outlook is entirely confined to hospital medicine, and the help they can give to the family doctor must be restricted because their advice can be framed only in terms of experience gained in institutions. With the help of the Postgraduate Federation, the universities, and the College of General Practitioners, general practitioner teachers may, within *the next few years, be able to offer a year’s training in* breadth to all those on their way up the rungs of the hospital ladder. And it may even be that a trainee assistantship in general practice may become an essential for the higher university and hospital clinical appointments.

CANCER AND ATHEROSCLEROSIS

FROM time to time pathologists have pointed out that patients dying of malignant disease have less atherosclerosis than those who die of other causes. The most obvious superficial explanation of this difference is that those with malignant disease may have lost more weight than the others, and Wilens[1] showed that at necropsy coronary atheroma was less severe in patients who had lost weight than in those who had not. The most evident difference between the two groups lay in the amount of lipoid infiltration, though there was also some difference in the amount of hyaline change and calcification.

Recent work has suggested that the obvious answer may not be the correct one. Elkeles[2] has approached the problem radiologically. Having previously found that patients with cancer of the stomach had much less calcification in their abdominal aortas than patients with gastric ulcer, he has gone on to consider the frequency of aortic calcification in patients with cancer elsewhere. 700 control cases were compared with 416 patients in the same age groups with proven malignant disease, and the amount of calcification was roughly graded by eye. In view of the possible dangers of observer error in such a subjective assessment, it might have been better to use a "blind" method of scrutiny. Nevertheless, the results seem quite clear. Calcification of the aorta was seen in just under 19% of the cancer group and in rather more than 35% of the control group. The difference was greatest in the patients aged 71–80, where 28% of the cancer group showed calcification, compared with 72% in the control group. Elkeles remarks that his results do not support the view that wasting is responsible for the reduced frequency of calcification in patients with cancer, but he gives no direct evidence to support this statement. The most interesting indication that wasting is not the true explanation comes from a comparison of the frequency of calcification in patients whose cancers arose from different primary sites. Calcification was seldom seen when the primary tumour was in the stomach, breast, or prostate, but when the primary site was in the respiratory tract, calcification was as common as it was in the control population. In general, this finding agrees with the results of Creed et al.,[3] who investigated the incidence and severity of aortic atheroma in a series of 1223 necropsies. They themselves examined only 167 of these specimens, the rest were evaluated from post-mortem records. Nevertheless, they felt confident enough to undertake a statistical assessment of the results. They found that patients who had died of bronchial carcinoma had the same degree of atherosclerosis as patients with hypertension, and significantly more than the control population. The severity of atherosclerosis was significantly less in patients who had died of leukæmia or malignant lymphoma. Surprisingly, patients who had lost weight rapidly before death showed more atherosclerosis than patients who had not lost weight, or who had lost weight slowly.

It is hard to draw any definite conclusions from these studies. Though some of the evidence is conflicting and insecure, it is clear that atherosclerosis and malignant disease are related in some peculiar way. It may well be that a better understanding of this relationship will lead to big advances in our knowledge of both types of disease, so that inquiries of this kind are of great importance. Because of the distribution of carcinoma of the stomach between the different blood groups[4] and the familial distribution of hypertension,[5] it is tempting to consider a genetic basis for the relationship, but a great deal of careful work is required before this idea can be seriously entertained. In the circumstances the anomalous position of bronchial carcinoma in relation to atherosclerosis might be attributed to extraneous carcinogens.

PROGRESS IN MICROSCOPY

POSSIBLY no single instrument has done more for medical and biological research than the microscope. After Zernike's development of the phase contrast microscope (a contribution recognised by the award of a Nobel prize in 1953) microscopy went through a stage of remarkable progress. The pace of discovery now seems to be slackening and it is possible to take stock. One way of doing so is to consult a useful series of thirteen articles, originally published in *Research*, which have now been reprinted as a small book.[1]

Electron microscopy, discussed by V E Cosslett, has been transformed by the development of methods for cutting sections of the order of one-fiftieth of a micron in thickness. This has led to such important advances in cell micromorphology that the electron microscope should become part of the routine equipment of every medical school. The chief use of reflecting microscopes, the subject of two contributions by K P Norris and E M F Roe, is in ultraviolet and infra-red microspectroscopy, from which valuable chemical information can often be derived about microscopic objects. Unfortunately the main sources of error in this technique as applied to cytology seem to lie in the nature of the specimen itself rather than in the optical system, and the results are not as accurate quantitatively as was once hoped. Of the many medical applications of fluorescence microscopy, reviewed by J King, the detection of tubercle bacilli is one of the most familiar. A promising technique is that in which proteins conjugated with fluorescent dyes are used to study antigen antibody reactions.[2]

The value of phase contrast microscopy in elucidating the structure of living cells is well known, but R Barer illustrates a less familiar use: it can give a quantitative measure of the refractive index of parts of living cells, and in this way the concentration of solids can be deduced. An application of special interest to pathologists is the measurement of hæmoglobin concentration in single red cells and the study of its distribution among different members of a red cell population. F H Smith describes several types of interference microscope, which give results broadly similar to phase contrast, but they can sometimes be used to measure optical path (i e, the product of refractive index and thickness)—a quantity which can be related to the dry mass per unit area, so that cells can now be "weighed" under the microscope. Refractometry and interferometry are closely related methods which may be expected to yield much useful quantitative cytological information. D Causeley and J Z Young describe the flying spot microscope, and they refer particularly to the counting of cells and particles. A red-cell count can be done in only four seconds, but the degree of consistency is perhaps a little disappointing. X ray microradiography, discussed in this book by W C Nixon, may prove useful in biology, not so much because of its resolving power (which is as yet only comparable to that of an optical microscope), as because it may reveal new types of contrast by displaying the relative opacity of some tissue constituents to X rays, though not necessarily to light. It is also particularly useful for three dimensional stereoscopic views of quite thick specimens. There are still many physical difficulties to be overcome, and long exposures of the order of several minutes are usually needed.

Microscopy is clearly very much alive and there are many new techniques waiting to be applied more widely in medicine

AUTO-ANTIBODIES IN RHEUMATISM

The hypothesis that rheumatic fever (and possibly other rheumatic diseases) are due to the presence of irregular antibodies to the patient's own tissues has always seemed attractive Cavelti[1] was among the first to claim the discovery of such "auto-antibodies" in the sera of patients with active rheumatic fever he used patients' serum and collodion particles sensitised with human heart antigen to demonstrate positive agglutination tests between the two, but Fischel and Pauli[2] were unable to confirm this work More recently, in Vienna, Steffan and his colleagues[3] have used a "Coombs reagent deviation test" to show that when a suspension of human heart tissue is incubated with serum from patients with active rheumatic endocarditis it absorbs a specific factor (presumably gamma globulin) from the serum A heart-tissue suspension treated in this way can significantly reduce the titre of a Coombs anti-human-globulin serum by absorption Similar "antibodies" reacting with mixed tissue suspensions of muscle, joint capsule, and heart were found in rheumatoid-arthritis sera by the same very indirect methods

Rejholec and Wagner,[4] in Prague, have now returned to the *collodion-particle technique in attempts to demonstrate* auto-antibodies in rheumatic-fever sera They sensitised collodion particles with saline extracts of mixed tissue from the organs of a cadaver—myocardium, heart valves, subcutaneous tissue, and joint capsules, and they noted that such "antigens" were very unstable and that preparations from many cadavers were unsatisfactory The sera of 38 patients with rheumatic fever were tested at various stages in the progress and treatment of the disease, and in each case the collodion-particle agglutination test was positive with at least one (and usually with all) of the "antigens" described, patients with clinical active myocarditis gave the highest titres The serum factor responsible for these reactions (whose specificity was controlled) was extremely unstable in vitro, disappearing within a week unless the sera were kept at −20°C This difficulty, and those inherent in the collodion particle agglutination method, make it unlikely that experiments will be attempted to correlate results obtained by this method and by that of Steffan

How far do such experiments substantiate an auto antibody hypothesis in rheumatic disease? It is doubtful whether the reactions attributed to rheumatic sera in experiments of this kind are really due to specific immunological phenomena The antigens presumed to take part in the reaction are completely uncharacterised, even in the broadest sense, muscle, heart valve, and joint capsule must share most of the body antigens between them It is perhaps useful to compare the present approach to the investigation of auto antibody formation as a cause of disease with that adopted in the probably related field of hypersensitivity The unravelling of the immunological fabric of allergy, while far from complete, owes much to the physical and biochemical characterisation of relevant antigens, which in turn has permitted quantitative and analytical study of serological activity in vivo and in vitro In the study of rheumatism, immunological research sadly lacks a defined antigen or group of antigens If, in fact, antigens do act as immuno logical *determinants of* rheumatism, real progress towards understanding its cause must await their identification

ANÆSTHESIA FOR BURNED CHILDREN

Because of the need for long and specialised treatment, children with severe burns are usually admitted to special units as soon as possible after the accident, and such units have their own anæsthetists But every anæsthetist should know how great the difficulties of anæsthetising a burned child can be, because the occasional case may reach any hospital

At the section of anæsthetics of the Royal Society of Medicine on Feb 1, Dr D W Shannon drew attention to the importance of resuscitation during the first forty eight hours after the child has been injured, when the difficulties to be met were those peculiar to resuscitation in children as well as those of the burns themselves When more than 10% of the skin area was damaged, the child's body could not adjust itself to the train of events set in motion, and unless treatment was begun rapidly and then sustained, deterioration would quickly set in Replacement of fluids and adequate oxygenation of the tissues were the twin essentials of therapy Burned children, Dr Shannon remarked, had a remarkable thirst for oxygen, arising not only from their normal physio logical requirements (which were much greater than those of adults) but from several factors, connected with burns, which were likely to affect respiration The respiratory muscles might be harmed, the air passages were often made œdematous by noxious fumes, spreading inflam matory œdema might press on the trachea, crusted sores in the neighbourhood of the nares often caused obstruction, and unwise dosage of drugs might induce a general depression Moreover, the whole picture was accentuated by oligæmic shock Effective resuscitation, with intravenous fluids and with oxygen, must therefore be supplemented by cutting down tissue needs, and strict curtailment of unnecessary movement and exami nation of the child was an important precaution

At the same meeting Dr H G Middleton emphasised that these children were likely to need many anæsthetics during their treatment, and familiarity with the anæs thetist (preferably in his theatre clothes during his visits between operations) was far better and often more effective than heavy premedication He also referred to the high incidence of other diseases in children who are burned—complications which in normal circumstances would suggest postponement of anæsthesia and operation until they had been treated But for the badly burned child, such complications must be accepted if life was to be saved Indeed, as the result of his analysis of the deaths at the Welsh Regional Burns Centre at Chepstow, Dr Middleton could exclude both anæsthesia and surgery as causes, in fact, he thought that they probably reduced immediate mortality

Unlike those who are being treated for many other emergencies, the "very poor risk" burned patient must be accepted for anæsthesia early if the mortality is to be reduced For the future, if the anæsthetist can keep his young patient alive during operation and immediately afterwards, then excision of full thickness burns, even earlier than is commonly done nowadays, might become the best treatment This would be a hard task, but the results would be even more rewarding than they are now

THE LANCET AIR-MAIL EDITION

We now print a small proportion of our weekly issue on India paper for transmission to distant countries by air The subscription rates for one year, inclusive of air mail postage, are

Australia and New Zealand	£13 13 0 (sterling)
United States, Canada, South Africa, and India	£11 11 0 (sterling)

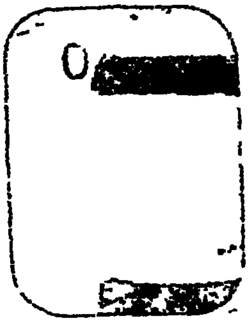
CASUAL EXPOSURE OF NURSES TO X RADIATION

B E GODFREY * S B OSBORN
B Sc Lond B Sc Lond, A Inst P
ASSISTANT PHYSICIST PRINCIPAL PHYSICIST

DAPHNE J TEMPLETON †
M S R
RADIOGRAPHER

PHYSICS DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL, LONDON

RADIATION-PROTECTION measurements in this hospital are largely carried out by means of film-badges, and those to whom they are issued include the nursing staff of wards where patients undergo treatment with radium and radio isotopes Most of these treatments are carried out in the special isotope ward, but occasionally such a patient may be nursed in one of the ordinary wards It has been noticed for some time that film-badges returned from these wards may show exposure to diagnostic X rays as well as to γ rays



The film badge holder contains two apertures through which radiation reaches the end sections of the film, the centre portion being screened by a filter. As the film is set about 1 mm behind the apertures radiation from different directions will be recorded in slightly different positions on the film We have found that exposure to diagnostic X radiation is usually at oblique angles Further, an X ray exposure, which is received in a short time and consists of low-energy radiation, appears as a clearly defined image, while γ-radiation in contrast appears as a diffuse image The accompanying figure is of a film showing these effects, in which the X-ray and γ-ray exposures can be measured separately, the appropriate calibration factor being used for each, Very few films show exposure to both X-ray and γ ray radiation so that in general X and γ ray exposures are easily estimated separately Table I summarises the information obtained from the film-badges issued in connection with radium and radio-isotope therapy over a period of 2 years

It is clear that if such exposure of nurses is typical of the nursing staff as a whole, the total amount of radiation involved is considerable Accordingly, an eight week test was arranged for two wards nursing surgical and radiotherapy patients The ward sisters knew that the object of the test was to ascertain the amount of diagnostic X radiation received by the nurses The rest of the nursing staff were not informed of the object of the test lest this knowledge should influence the result During the eight week period a scalp treatment with a radium mould was carried out in ward A, and a colloidal radio gold treatment in ward B, for which film badges would have been issued in any case Coöperation was excellent and the results obtained are shown in table II For comparison similar data from other departments over a period of two years are shown in table III

Doses Received

It is clear that the amount of radiation received is substantial, but it is unlikely that the results in table II are typical of the nursing staff as a whole The two wards investigated nurse a substantial number of patients who have undergone major chest surgery, and many of them have chest radiographs taken in the ward repeatedly, although the amount of such work during this particular period of eight weeks was considerably less than average If such an examination is undertaken in the few days following the operation, up to three nurses may be required to hold patient and film, and they are almost bound to be exposed to some of the direct beam of radiation The extent of this is shown by the observation that 5 out of the 137 film-badges recorded more than 300mr in one week That is, on average each nurse in these wards may expect to receive an occupational exposure of more than 300mr not less than 1 week in 28 or at least twice a year Further, the average amount of radiation per nurse-week is about 20mr The International Commission on Radiological Protection (1955) recommends that radiation workers should not receive more than 300mr per week where a substantial fraction of the body is irradiated For large populations (i e, groups of people not subject to the rigorous control specified for radiation workers) exposure should not exceed 30mr per week On the average, this condition is just fulfilled The average dose-rate of 20mr per week, as will be seen from table III, is considerably higher than that received by several groups of radiation workers in the same hospital

TABLE I—ANALYSIS OF 575 FILM-BADGES WORN BY THE NURSING STAFF IN CONNECTION WITH RADIO-ISOTOPE AND RADIUM TREATMENTS, OVER A PERIOD OF TWO YEARS

Ward	No of films issued	% of films showing exposure	Average recorded dose (mr)	Average dose per nurse-week (mr)	Number of nurses at risk
Isotope ward	455				8
X radiation		6 2	44	3	
γ radiation		59	10	6	
Other wards	120				800*
X radiation		13 3	77	10	
γ radiation		33	20	7†	

* Average number of nurses on *all* other wards who could be exposed to X radiation

† Average γ ray exposure per nurse week during radium and radio isotope treatments only

On average, a nurse is unlikely to receive as much as 30mr per week (ward A, table II) or as little as 3mr per

TABLE II—ANALYSIS OF 137 FILM-BADGES WORN BY NURSES ON TWO SURGICAL WARDS DURING AN 8 WEEK TEST WITH COMPARABLE FIGURES FOR THE ISOTOPE WARD FOR THE SAME PERIOD

Ward	% of films showing exposure	Average recorded exposure (mr)	Average dose per nurse week (mr)	Highest individual average* (mr per week)	Highest recorded dose † (mr)	No of times 300mr per week exceeded
Surgical A						
X radiation	33	89	30	220	350	4

week (isotope ward, table I) The values of 10mr per week (other wards, table I) and 13mr per week (ward B, table II) are more likely to be typical All γ radiation received by the nursing staff from radio isotope therapy is accounted for, and over the whole group of 800 nurses amounts to an average of only 0 1mr per week The X radiation amounts to about 10mr per week, and both these figures must be compared with the natural radiation level of about 2mr per week (Spiers 1956) No doubt the amount of X radiation could be considerably reduced by accurate coning, but this is of necessity much more difficult in ward radiography than it is in the X-ray department itself The extensive use of clamps and mechanical aids would reduce the need for the holding of patients and films by hand

TABLE III—ANALYSIS OF 6160 FILM BADGE RECORDS OVER A PERIOD OF 2 YEARS

Department	Average dose (mr per week)	Highest weekly average* (mr per week)	Highest dose in any one week (mr)	% of films recording at least 300 mr	Approximate no of measurements	Approximate no of staff
Isotope ward	9	30	80		460	8

Deliberate Exposure

There is bound to remain the occasional case where a nurse must hold the patient or film If, in such a case, radiological examination is essential, the nurse should be provided with a lead rubber apron and lead rubber gloves There is no more valid reason for exposing a nurse to a primary beam than there is for a radiographer

It has for long been the custom, in both diagnostic and therapeutic radiology, for the radiographer to ask relatives or ward nurses to hold a patient in the beam of radiation, where this is essential This practice is clearly preferable to repeated exposures of the radiographic staff to the primary beam It is presumably based on the assumption that exposure of the nurse or relative will be a relatively infrequent occurrence and the effects negligible In view of recent evidence on radiation exposure levels in this country (Medical Research Council 1956), particularly the increasing number of diagnostic X ray examinations (Osborn and Smith 1956) and the induction of leukæmia by radiation (Court Brown and Doll 1956), this practice may need to be modified

We wish to record our thanks to Miss H M Downton, matron of University College Hospital, for her help in this work, and to Miss D W Cook and Miss J G Price, ward sisters, for their active collaboration Miss I Bull, M S R, gave invaluable help in the film badge measurements

JOINT CONSULTANTS COMMITTEE

A MEETING of this committee was held in London on Jan 23, with Sir Russell Brain in the chair

Medical Membership of Hospital Boards

Among the matters under consideration was a circular issued by the Ministry of Health on Dec 31 informing hospital boards that the Minister had accepted the recommendation of the Guillebaud Committee that the medical membership of regional hospital boards should not exceed 25% of the total membership save in quite exceptional circumstances, and advising boards to observe the same principle in making appointments to hospital management committees The Joint Committee had previously urged the Ministry that the membership of a regional board should include at least 5 consultants actively engaged in the region concerned, and in addition a general practitioner and a medical officer of health, all nominated by the profession In a letter from the Ministry informing the committee of the Minister's decision it was stated that the Minister could not accept this proposal, but that he fully shared the committee's view that the medical members of the regional boards should consist primarily of active members of the consultant staff in the region, together with a general practitioner and a medical officer of health

The Joint Committee was profoundly disturbed at the Minister's decision, the more so as it appeared inconsistent with his acceptance of the principle that the medical membership should consist primarily of active members of the consultant staff in the region, who are by no means well represented on regional boards at the present time The committee thought it inevitable that the small number of consultants representative of those working in the regions must be still further reduced if the over-all number of medical members was to be reduced, while still including representatives of the universities and medical schools, and in addition a general practitioner and a medical officer of health

The committee felt strongly that any reduction in the medical membership of hospital boards would, of necessity, effect adversely the valuable part played by the profession in the administration and planning of the service, and that to place upon a smaller number of doctors the responsibility of serving on the boards and their various committees would make the burden intolerable

The committee decided, therefore, to ask the Ministry for an early opportunity of discussing the matter further It decided also to discuss with the Ministry again the question of medical advisory machinery at regional board level, in the light of the recommendations of the Guillebaud Committee, while making it clear that it did not regard such machinery in any way as an alternative to adequate representation on regional boards

Hospital Medical Staffs

Representatives from the registrars group of the British Medical Association attended the meeting to put before the Joint Committee their views regarding the problems associated with hospital medical staffing as they affected the prospects of registrars and senior registrars They pointed out that the salary scales recommended by the Spens Committee had been formulated on the assumption that consultant status would normally be reached at 32 years of age At the present time, however, senior registrars in the main specialties did not usually obtain their first consultant appointment until several years later than this, with a consequent loss in their total life earnings of £1700 for every year promotion was delayed beyond the age of 32 They urged that the introduction of a new career grade below consultant status would not provide a satisfactory solution of the problem since it would permanently lower the total life earnings of a proportion of new entrants into the hospital service They recommended that there should be a gradual run-down in the number of senior registrars which would ensure reasonable prospects of promotion after an average training period of four years Pending such a balance being obtained, and as a purely temporary expedient, they suggested that the tenure and salary scale of time-expired senior registrars should be extended, and newly appointed consultants given seniority on the incremental scale for every year over 32 at the time of appointment

Appointments in Venereology

A deputation from the venereologists group committee also attended the meeting to discuss with the committee the difficulties experienced in the staffing of venereal-diseases departments in areas where there is insufficient work to make a consultant appointment in the specialty practicable

Moral Obligation

The committee agreed to a proposal from the Ministry that the Appointment of Specialists Regulations should be amended to allow a consultant or senior hospital medical officer whose sessions are reduced, or whose contract is terminated through redundancy, to be offered an alternative appointment without the necessity to apply for the vacancy in open competition

Hospital Private Beds

The question of the steadily rising charges for hospital private beds was discussed and the committee decided to prepare a case for the introduction of a moderately priced private bed Reference was also made to the many anomalies in the schedules of operations contained in the Pay Bed Regulations, and instances were quoted of the way in which these schedules operated to the disadvantage of the patient rather than to his advantage It was agreed to submit a reasoned case to the Ministry for the abolition of the schedules

Other Matters

Among other matters discussed were the shortage of radiographers and physiotherapists, domiciliary consultations by pathologists the attendance of chairmen of hospital group medical advisory committees at meetings of hospital management committees, and the payment of fees for the examination of prospective employees at the request of employers

N H S SUPPLEMENTARY ESTIMATE

ACCORDING to the Supplementary Estimates,[1] published last week, a further £26,872,700 will be needed for the National Health Service in Britain in the present financial year This brings the net total cost to £529,014,830 An additional £15,008,000 is needed by hospital authorities, mainly to cover increases in remuneration, prices, and rates For the pharmaceutical services an additional £8,089,000 is needed, despite the change in charges (from Dec 1 last) from 1*s* per form to 1*s* per prescription The estimated total of payments to general medical practitioners is increased by £2,946,000, and that of payments to general dental practitioners by £1,635,000

MORTALITY A CHANGING PATTERN

J A FARRER

M B Melb

RECLINING peacefully in many a village church are records which go back many years before the introduction of our more up to date registration statistics

When we speak in terms of advancement in ways of living, with what are we comparing the present day? In fact what, in our present day, are we to compare? Are we to compare recent statistics with past impressions, or do we put our impressions into statistics and compare them with the impressions of the great novelists?

Because of the high proportion of intangibles, there are many difficulties in the way of anyone wishing to project the past on to the present However, from the following, relatively small exercise, I wish to draw attention to possibilities which others, more skilled than I and with access to more extensive records than I, may care to follow up

The material consists of the record of burials performed in a very rural Dales village[1] At first sight the books, with their parchment pages, appear only relevant to those wishing to seek information on the whereabouts of their ancestors But, from the year 1804, the ages at death have been inserted and it is from that time that my tables have been constructed

The first nine years' recording is somewhat more interesting in that the diagnosis has been inserted

Tables I–III show the number of deaths in each age-group the percentage which this number represents of the total deaths in this period, the actual numbers of male and female deaths, and the ratio of male to female deaths Table IV shows the deaths in 1953 in the whole

TABLE I—DEATHS IN CLAPHAM CUM NEWBY (1804–12)

Age group	Total	% of total	Males	Females	Ratio males	Ratio females
0–5	66	20 2	35	31	53	47
5–10	12	3 7	4	8	33 3	66 7
10–20	30	9 2	15	15	50	50
20–30	23	7 1	9	14	39 1	60 9
30–40	24	7 3	10	14	41 6	58 4
40–50	23	7 1	12	11	52	48
50–60	20	6 1	9	11	45	55
60–70	30	9 2	19	11	63 4	36 6
70–80	52	15 9	24	28	46	54
80–90	39	11 9	17	22	43 6	56 4
90–100	8	2 4	6	2	75	25
	327					

TABLE II—DEATHS IN CLAPHAM CUM-NEWBY (1813–37)

Age group	Total	% of total	Males	Females	Ratio males	Ratio females

[1] Church Records Clapham-cum Newby Parish Church 1804–63

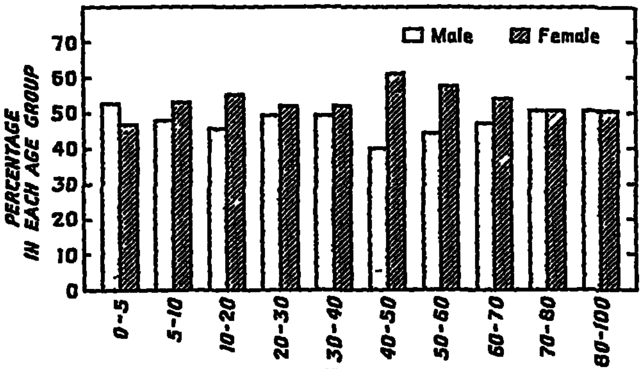

Fig 1—Ratio of male to female deaths in Clapham-cum Newby (1804-1865)

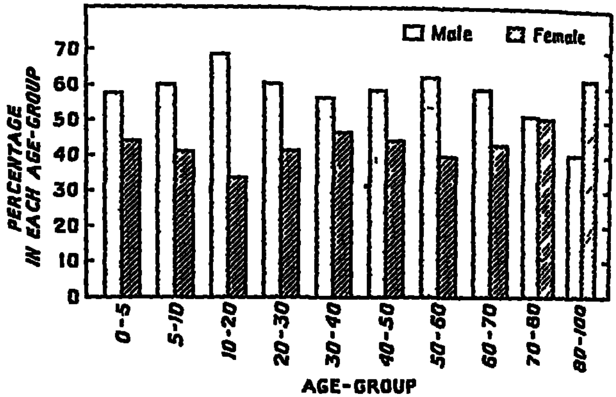

Fig 2—Ratio of male to female deaths in England and Wales (1953)

country,[2] From the totals in tables I–III, fig 1 was constructed This shows

1 In most age groups, female deaths predominate, the exceptions being a reversal in the first age group and equality in the last two

2 The only considerable sex difference is in the age groups 40–50

3 The sex difference in the age groups 20–40 is comparable with the total sex difference (48 4 male to 51 6 female)

TABLE IV—DEATHS IN ENGLAND AND WALES (1953)

Age group	Total	% of total	Males	Females	Ratio males	Ratio females
0–5	21,528	4 21	12 244	9284	56 7	43 3
5–10	1763	0 33	1043	720	59 2	40 8
10–20	2899	0 575	1769	1130	61 0	39 0
20–30	5967	1 18	3572	2395	59 8	40 2
30–40	10 132	2 01	5517	4615	55 5	45 5
40–50	24 738	4 9	14,120	10,618	57 4	43 1
50–60	54 994	10 9	33,711	21 283	61 2	38 8
60–70	105 160	20 9	61,094	44 066	58	42
70–80	159 165	31 5	79,806	79 359	50 2	49 8
80–100	117,183	23 2	46,614	70 569	39 7	60 3
	503,529					

Table IV, as prepared for 1953, has been represented in fig 2 The first item of note is, of course, a reversal of the proportion of male to female deaths Secondly, the whole pattern of ratios has changed

Lastly the tables have all been combined to show the changing pattern in another aspect (fig 3) This figure is based on the third column of the tables I, II, and III are reduced to a single set of figures represented by the white portions, and table IV is represented by the black portions

This bears out the general impression that mortality during the earlier years, particularly the first year of life, has been reduced

Discussion

When I began to examine these records I had very little idea whether anything of interest could be obtained But by the time the first three tables had been prepared, it became evident that, in spite of the relatively small numbers, there was a consistency in percentages (third column) over the years taken This consistency is also present, though not so exact, in the final column (ratio of males to females)

This pattern, I felt, could best be expressed in comparison with the present day figures shown in fig 3 but needed a rearrangement of the numbers for 1953 to make the scale comparable

When these had been completed, the next point meriting attention was the recording of the years 1804–12—the only years for which a diagnosis of the cause of death was recorded When the record had been prepared, it was evident that, though it was extremely interesting, no actual conclusions could be drawn

I had always thought that the rigours of childbirth had contributed largely to the mortality of the early 19th century yet in this series of some 327 deaths, only 2 were directly attributed to childbirth We must, of course, be careful in drawing general conclusions because medical knowledge has increased, but the records of births

TABLE V—CAUSES OF MORTALITY IN CLAPHAM CUM-NEWBY (1804–12)

Age group	0–5	5–10	10–20	20–30	30–40	40–50	50–60	60–70	70–80	80–90	90–100

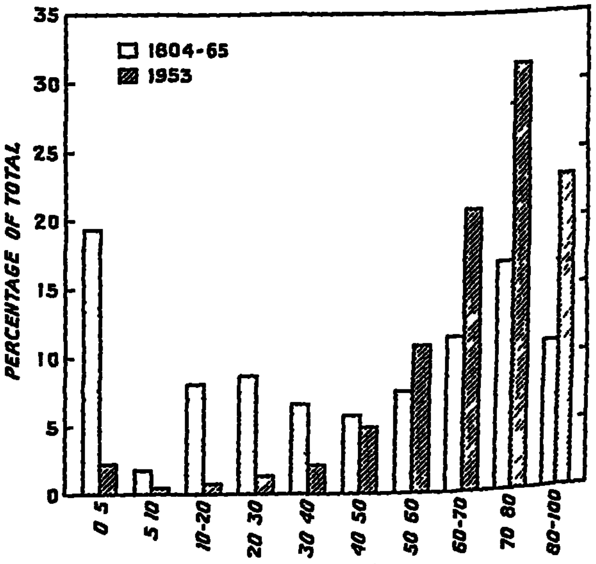

Fig 3—Ratio of deaths in Clapham cum Newby (1804-1865) to deaths in England and Wales (1953)

confirm that the small number of deaths in childbirth may well be accurate

---

[2] The Registrar General's Statistical Review of England and Wales for the year 1953 Part I—Medical H M Stationery Office 1954 Table 16

Figs 1 and 2 show the pattern of male and female deaths for the period 1804–65, as compared with 1953 There is an alteration in the pattern which is hard to explain Part is, of course, accounted for by the fact that we are living in an era of more male births, in Clapham as in the rest of the country

Perhaps others may care to comment, or search

My thanks are due to the Rev C T Foster for permission to examine the records

Before Our Time

Thomas Lawrence

AT a meeting of the Osler Club held at the Royal College of Physicians on Jan 24, with Dr W S C Copeman, president of the club, in the chair, an address on Dr Thomas Lawrence was given by Sir Russell Brain, P R C P

Lawrence, he said, was born in 1711 into a family which played some part in national affairs from the middle of the 16th to the beginning of the 19th century His grandfather was physician to Queen Anne, and his father a captain in the Royal Navy Thomas Lawrence went to Trinity College, Oxford, decided to take up medicine, and became a student at St Thomas's Hospital and a pupil of Dr Nicholls, the popular lecturer in anatomy, whom he succeeded in that position at Oxford He also lectured in anatomy in London until he was displaced by the popularity of Hunter He then devoted himself to practice, and occupied numerous positions at the Royal College of Physicians, being elected president in 1767

The college library contains a number of Lawrence's works, both Latin and English Perhaps the most interesting is the *De Natura Animali* to which has been attached the manuscripts of Dr Johnson's corrections of Lawrence's Latin Lawrence's knowledge of anatomy is illustrated by his lectures, and his philosophical outlook by his discussions on the relation between the mind and the body

His election as president took place during the turmoil of the famous siege of Warwick Lane, when the Society of Collegiate Physicians, in protest against the tradition that only graduates of Oxford and Cambridge could become fellows of the College, broke in by force and attempted to take their places in comitia

Lawrence is known to us chiefly because of his friendship with Johnson, whose medical attendant he was Both Johnson's letters and Mrs Thrale's writings contain numerous references to him Both men were in failing health when Mrs Thrale accompanied Johnson to consult Lawrence who had that morning had a slight stroke She gives a graphic account of the interview Lawrence, who had suffered from angina as well as repeated slight strokes, retired from practice to Canterbury in 1782, and died there in the following year He was buried in the church of St Margaret, and a memorial tablet, with a portrait in relief, was placed in Canterbury Cathedral by his surviving children

Seeing Lawrence through the eyes of his contemporaries, we can construct a fairly complete picture of his personality He was a gentle, scholarly man whose hobbies were building model boats and playing the cello "In his endeavours to attain to eminence," writes Hawkins, "it was his misfortune to fail he was above those arts by which popularity is acquired and had besides some personal defects and habits which stood in his way a vacuity of countenance very unfavourable to an opinion of his learning or sagacity, and certain convulsive movements of the head and features that gave pain to the beholders and drew off attention to all that he said "

This address will appear in *Medical History* (see p 381)

The Widdicombe File

XXXVIII CURRICULOSIS

DEAR JAMES,

MY fraternal greetings I write to you however not as a brother but as, since your last Widdicombe, an accepted authority on the curriculum The G M C is thinking of relaxing its dead and iron hand and the Royal College of Physicians has set up its conference on medical education I hope they have had the sense to include you

The old war cries will soon be filling the air again—integration, correlation, the holistic approach, the basic validity of the doctor-patient confrontation and so on and so on Like you, I sniff the battle from afar and long to be doing, but, compared to you, I may not be quite so well pleased to have my piece listened to I began to compose you a memorandum, on such delectable topics as the need to retain the sixth year, and the introduction of a sixth year multiple option honours course for those who can complete the ordinary course in five years, and the black heresy of those who regard morbid anatomy as a dead subject But I became a little discouraged after a while all these things had been said before, and anyhow what did it matter? How much does the curriculum affect what we teach and what the student learns? I begin to believe that it matters a good deal less than the disputants pretend

Don't get me too far wrong Anyone who puts forward the current curriculum of any British medical school as an ideal which couldn't be improved is an idiot But I want to put forward some arguments, which are, I think, at least in part a poor thing, an ill favoured thing, Sir, but mine own, for the view that the curriculum has far less influence on the final content of the student's head (which is after all what matters) than we generally assume And the gist of the argument is simply this that this final content of the student's head reflects most closely not what his teachers taught him of their own subjects, but what they taught him of every subject but their own

Let me take your own subject of bacteriology We and you and most schools take a middle-of-the road view we teach a middling amount of bacteriology near the middle of the course But if we were radically minded we could find arguments for putting bacteriology anywhere in the course from preregistration to final year You could I am sure find excellent grounds for supporting a proposal to devote a full year of the medical course exclusively to microbiology I could on the other hand find excellent grounds (the proper study of mankind is man) for excluding it, as a separate discipline, from the course altogether I don't want to consider these arguments what I want to suggest is that, whether you taught bacteriology for three solid terms in the second year or I confined you to three optional lectures on epidemiology in the final year, the end result would not be so very different

You teach your bacteriology—and remember again that I'm taking this subject only as an example—to your students, James, in three principal ways There's the direct, the lectures you give yourself There's the deputy direct, by which I mean the lectures and practical classes and seminars given by your deputies, the junior members of your own department And there's the indirect the bacteriology that reaches them through those of their teachers who are not bacteriologists

It's not difficult to show that the second is more important than the first Partly it's quantitative: unless you're grossly understaffed your students will see far more of your juniors, and in far smaller groups, than they do of you no matter how much more practised and eloquent a teacher you are you are unlikely to overcome the sheer weight of numbers But there's a more subtle factor Your efficiency and your stature make what you say, however you strive against it, an Olympian utterance—something that must be true, something to be memorised rather than thought about Your rawest demonstrator is to the student someone human who can be wrong, who can be challenged and questioned The material he presents is only half digested and the very effort the student makes to digest it himself, though it wastes most of it, means that some will stick and stick for ever And so it comes about, James, that what you teach that same raw demonstrator is far more important than what you teach your students yourself

The importance of the third kind of teaching is perhaps not so evident But it works out I think something like this What you or even the youngest of your assistants teaches has always about it, however hard you try to get away from it, a faint aura of professionalism and laboratory unreality This isn't what proper doctors *think, this is just what bacteriologists think* It's to be swotted up for 3rd M B, then forgotten as soon as possible What is remembered, and remembered long after 3rd M B and Final as well, is the odd occasion on the ward when the report from the lab is awaited anxiously, when the textbook mumbo jumbo of *B thingumibobbii* and rising titres and falling sensitivities proves to mean something in terms of handling the patient, and when the clinician turns out to understand more than a little of what it is all about *That* part of bacteriology seems at once significant, something to *hold on to* And the same thing applies to other subjects Certainly to pathology—it's not what I teach them but what the surgeons and physicians and anatomists and bacteriologists teach them that sticks best Even among the clinicians it applies the smatterings of surgery retained by the physicians and of physician's medicine by the surgeons, the cardiology of the urologist and the neurology of the obstetrician, these irreducible minima of knowledge that seem to the student to be possessed by all his teachers, it is these that—rightly enough when you come to think of it—he regards as the irreducible *minima of* what he *must* learn himself If Sir Daniel Whiddon knows about the Nagler reaction, it must be important if not, who is the student to set himself up as better than Sir Daniel? And, *per contra*, if you or I don't know the difference between a Billroth I and a Billroth II, why should he worry about it?

There is a corpus of knowledge in every medical school, a highest common factor in the knowledge of all its teachers, that is by far the biggest single factor in forming and in stocking the minds of the students we produce It is repeated to him again and again under different disguises by different teachers (the Bellmen crying "what we tell you three times is true") and cannot but sink in *It is a prime responsibility* of every member of the staff to see that this corpus is kept alive and true and reasonably up to date To contribute effectively to this corpus you need three things you must have knowledge to contribute, you must have contact with the rest of the staff, and you must be successful as a practitioner of your own particular trade

The last is important The doctrines of the surgeon or physician whose patients do not get well, of the pathologist or radiologist whose diagnoses need too frequent revision, are always suspect It is in this that one of the chief dangers of the "pure" research worker in charge of a department lies His colleagues, unable to judge him by the pragmatic test of the success of his *ideas in practice, are slow in learning to trust him* as a source of information If he's outstandingly good of course, bridges will in time be built But in general a department devoted to pure research is almost as dead a loss to its medical school as one that does none at all (I think this even applies to the preclinical departments, which ought *somehow* to be brought into the hospital, but that is another story)

The value of clinicopathological conferences and the like lies chiefly in their hot-house forcing of this corporate knowledge in the staff of the school A student audience is only an excuse for a C P C it's the staff (on both sides) who are really educated

In this respect a medical school mirrors on a smaller scale the university of which it is a part You can have a university with no students, but you cannot have a university with less than three faculties The interchange of ideas between different disciplines is infinitely more important to the idea of a university than extremes of accomplishment in any one of them Moreover, though any cram college can teach students after a fashion, only a university can teach teachers It is a self-propagating enzyme system (that is the reason for its immortality) the proper nurture of its brighter entrants to take the place of their teachers is its one altogether inescapable function The teaching of the rest of the students is merely a valuable by-product They come to warm themselves at a fire they will never feed

As the head of a university department you have five main duties (I leave out administration, for that is only a means to the other ends) The first and chief is to be a good bacteriologist yourself The second is to teach your staff to be good bacteriologists in their turn The third is to communicate a distillate of your knowledge to your colleagues in other departments The fourth is to join in the education of whatever students come before you, adapting your instruction to the stage of their progress through the curriculum (remembering that, if there's anything in *what* I've *just said, it's* the interlarded fragments of pathology and pædiatrics and plumbing that they will remember best) The fifth and last and leastest, is to arrange the base details of that curriculum

The reorganiser of the curriculum is like a time and motion engineer in a watch factory he can save time, and produce a cheaper watch, but he cannot produce a better watch A reorganised curriculum may save time and energy, but it will not alter what is in the teachers' heads and it is what flows out of the full head of the teacher into the empty head of the student that matters, not the channels we contrive for the flow

You may say that in one respect the curriculum may circumvent this, if it cannot affect the contents of the head of the individual teacher, it can decide which teachers are to do the teaching It's partly true of course by adding or subtracting subjects we add or subtract teachers But even that is not as decisive as it sounds

Consider an extreme example we've already cited If you captured a whole year of the course for bacteriology, *you'd get wonderful results in 3rd M B*, but six months *later* you'd find it nine-tenths *forgotten* (just as now you can watch recent victors of 2nd M B visibly stripping themselves of superfluous anatomy till they arrive at the level their teachers of the clinical years seem to find adequate) But if, on the other hand, you were not allowed to teach any bacteriology, teachers of other subjects would find they had to introduce it into their own courses (As once at school, our maths being behind hand, our chemistry master taught us logs and our physics master nearly got us as far as calculus) Except for a few enthusiasts the first method would give you, the end results wouldn't be as grossly divergent as you might suppose Bacteriology is a necessary part of medicine, in that respect it arranges for its own teaching

It is much the same with new subjects If they are good and live and genuine they edge their way in willy-nilly Students listen avidly, teachers find it profitable to display their erudition on something outside their usual sphere The best registrars suddenly start side stepping into the novelty, and in self-defence the school has to appoint someone to its staff to take care of it It is being taught as much as it deserves usually long before the curriculum has even noticed it exists

Good luck to your discussion, James, I'm sure the grand debate will be the better of your contribution But don't waste too much time on it Remember only, as the Inquisitor nearly said, that bacteriology comes first

Yours,
PETER DAVEY

Parliament

Capital Punishment

ON Feb 1 the debate on the first private member's Bill of the day—a measure for the control of hire-purchase advertisements—lasted for five hours As a result of this exhaustive discussion the private member's Bill to abolish hanging lost its slender chance of survival On Feb 6 the third reading of the Government's Homicide Bill, which restricts but retains the use of capital punishment, was carried by 217 votes to 131, and sent to the House of Lords

In introducing the third reading Mr R A BUTLER, in his first speech as Home Secretary, said that the new defence provided in clause 2 would enable the courts to take account of the great strides that had been made in the understanding of the human mind, and to avoid treating as murder killings for which the accused ought not to be held wholly responsible This was part of the new approach to the problems of the mind which he thought would exercise both the Home Office and the House in the coming months and years He believed that the unexplored territory of the mind would be perhaps one of the most exciting of the adventures before the human intellect in the years to come, and as important in our relationships in the human sphere as nuclear development in the scientific He hoped that he might have the support of the House in any further moves in this direction in the humanising and understanding of relationships, whether in crime or in the other spheres for which he was responsible

In the course of the debate Dr REGINALD BENNETT returned to this clause about which he confessed he felt uneasy The new code on diminished responsibility seemed to him in conflict with the McNaughten rules yet the rules had not been abolished He feared that the courts in future would be baffled which of these mechanisms was to be invoked in murder trials If there was a prima-facie abnormality of mind did a charge of murder still stand? Or, if it was evident from unopposed medical evidence before a trial came to pass that the prisoner's mental condition was in other ways deranged, did the indictment drop to that of manslaughter? If there was a charge of murder, must the outcome of the charge be either that the prisoner was unfit to plead on arraignment —that he was guilty or not guilty or that he was guilty but insane—or was there the further alternative, when the charge was murder that he was guilty of manslaughter? Or did he really go for trial on a charge of manslaughter to which he could be guilty or not guilty?

An even greater difficulty, Dr Bennett suggested, was to decide on what basis and to what degree there was irresponsibility The provision in clause 2, was whether the accused

> " was suffering from such abnormality of mind (whether arising from a condition of arrested or retarded development of mind or any inherent causes or induced by disease or injury) as substantially impaired his mental responsibility for his acts and omissions "

Against that we had the McNaughten rules, which asked whether the accused was suffering at the time from such a defect of mind as to be unable to appreciate the nature of his act or the fact that it was wrong Which of these two standards came first? Did one supersede the other? Might it be assumed that in future in cases of homicide there would be no consideration of the McNaughten rules? The point was important because if the McNaughten rules applied, a man found to be suffering from a defect of reason would go to Broadmoor which was automatically an indefinite sentence If, however, his defect of mind was found to be one which justified a sentence for manslaughter, there would be no consideration of any treatment for his mental state except such as is incidental to an ordinary term of imprisonment

In winding up the debate Mr J E S SIMON, the joint under-secretary of State for the Home Office, said that the Bill provided a criterion which took cognisance of the fact that there were, humanly speaking, many degrees of mental responsibility for crime Till now the only legal criterion of mental responsibility for crime was provided by the McNaughten rules, and unless that rigorous test was satisfied, the death sentence was passed The Home Secretary, in deciding whether to recommend that the sentence should stand, applied a different test and one not prescribed by the law The Bill went far to reconcile that divergence

Turning to Dr Bennett's question as to the relationship between the two defences, Mr Simon said that the accused man might, on the face of it, be unfit to plead That was generally a matter which was initially determined by the prosecution, though it might be raised by the defence, and a jury was then empanelled to decide whether the man was fit or unfit to plead It was only if the man was fit to plead that any question of these defences arose, and then it was a matter for the man The prosecution could not raise any question at that stage as to his mental responsibility for the crime It was for him to say whether he would raise a defence which would lead to a verdict of "Guilty but insane" or whether he would raise the sort of defence which would lead to a verdict of manslaughter by raising a question of diminished responsibility The one was under the McNaughten rules It was a complete defence and the verdict was guilty but insane, which was equivalent to not guilty The diminished responsibility defence would lead to a verdict of guilty but guilty of manslaughter For this the sentence was not necessarily a fixed term It was a matter for the judge's discretion, on the evidence that was then given to him after the verdict, as to whether he passed a sentence for life if he could not determine the time necessary successfully to treat the prisoner He could sentence the convicted man to a term of years Equally he could, if he wished, put him on probation for the crime of manslaughter, and he could make a condition of the probation in a proper case that the man should submit himself to psychiatric treatment, or, indeed, any other medical treatment for a suitable time

Domiciliary Services for Old People

On Feb 6, under the ten-minute rule, Mr FRANK MCLEAVY introduced a Bill to amend section 31 of the National Assistance Act, 1948, so as to empower local authorities to provide meals and domiciliary and other facilities for old people

QUESTION TIME

Supplementary Estimate

Mr ARTHUR BLENKINSOP asked the Minister of Health how much of the Supplementary Estimate for the National Health Service was due to an increase in the number of medical and other staff of our hospitals —Mr DENNIS VOSPER replied None Provision for staff increases was made in the original estimate *With* insignificant exceptions, the extra expenditure on hospital running costs provided for in the Supplementary Estimate is in respect of increases in pay, prices and rates

Number of Prescriptions

Mrs L Jeger asked the Minister the number of prescriptions dispensed during the first month of the new charges, and the number for the corresponding period last year —Mr Vosper replied *An accurate figure is not yet available* From a representative sample it is estimated that the number dispensed in England and Wales during December, 1956, was of the order of 15 5 million The total number in December, 1955, was 19,349,115

Dental Hygienists

Mr Barnett Janner asked the Minister, as representing the Lord President of the Council, whether he would make a statement on the availability of dental hygienists for the general public in accordance with the provisions of the Dentists Act, 1956

Mr Vosper replied Some dental hygienists are already employed in the local authority and hospital dental services, but they cannot work with dentists in private practice until permitted by regulations made under the Dentists Act, 1956, by the General Dental Council The General Dental Council has asked the Privy Council to approve draft regulations which provide that dental hygienists shall not be allowed to work in private practice until such time as the requirements of the local authority and hospital dental services are, in the opinion of the General Dental Council, satisfied This limitation would not appear to accord with the intentions of Parliament as expressed during the passage of the Bill and the proposals have therefore been referred back to the General Dental Council for further consideration

Fees for Poliomyelitis Vaccination

Mr Moss Turner Samuels asked the Minister of Health whether, in view of the fact that the remuneration of general practitioners for the carrying out of the responsible duties and complicated arrangements required to collect, store, and administer the vaccine and keep the necessary records in connection with inoculation against poliomyelitis was unreasonably low, he would increase the present inclusive fee of 5*s* for the two inoculations required in each case to a more reasonable figure —Mr Vosper replied The vaccination will be performed as part of the general practitioner's comprehensive medical care of his patients for which he receives remuneration from his local executive council, the additional 5*s* fee is to be paid by the local health authority for the record of vaccination This is the present fee for records of other forms of immunisation and was agreed between representatives of local authorities and of the medical profession

Overseas Dental Students

Mrs Hill asked the Minister of Health how many students at present in British dental schools are from the Commonwealth and how many from foreign countries, and how many he estimates will practise in this country after qualifying —Mr Vosper replied The numbers from Commonwealth and foreign countries in English dental schools are 109 and 113, respectively I cannot estimate how many will practise in this country after qualifying

Senior Medical Inspector of Factories

Sir Leslie Plummer asked the Minister of Labour if he would now improve the grading of the post of H M Senior Medical Inspector of Factories, to reflect more accurately the importance attached to industrial health organisations and equated with the grading of the chief medical officer of the Ministry of Pensions and National Insurance and of the Colonial Office as well as with the Treasury medical adviser —Mr Iain Macleod replied *No* The present grading of the post of H M Senior Medical Inspector of Factories is based upon the recommendations of the Howitt Committee which reported in 1951 The salary has been adjusted in accordance with the recommendations of the Royal Commission on the Civil Service

Occupation Centres for Mentally Handicapped

At the end of 1955, 12,372 mentally handicapped people were attending occupation centres and 7877 others, mostly adult, were reported by local authorities to be suitable to attend when places could be provided At the end of 1956 there were 301 centres in full time and 69 in part time use Schemes for 41 full time centres have been approved and these may be expected to be working in the course of the next two years Proposals for 33 others are being considered

In England Now

A Running Commentary by Peripatetic Correspondent

You might think that transplanting a couple of gooseberry bushes a simple operation ? Not in our garden I was poised with my fork when the dustmen arrived and amongst them my old patient Tom Hoggart

" Are t' movin' goosegogs, doctor ? "

"-Yes, into the orchard, Tom "

" Thou'lt send 'em to their grave "

" Eh ? "

" Th' acid in t'ground They might show first year, small an' 'ard Followin' year they'll wither down Th' acid 'l draw 'em down to t'root ends "

At that moment my wife came rushing out of the house her hands and arms white with flour

" You're not moving the gooseberry bushes are you ?

" Why not ? "

" Every time anything looks as though it's going to take a hold in this garden you decide to move it Even weeds can't grow here, they haven't time "

" Relax, honey-child In three years these two bushes have produced five hard, hairy goosegogs They need a new start And that's what I'm giving them ! "

" It will be the children next," she said " You'll be sending them to boarding school "

As our eldest child is only $3^1/_2$ I considered this a remark of quite tangential irrelevance and was about to say so when Mr McGillivary, the smith, walked by I was in need of an ally

" Moving the gooseberry bushes, doctor ? "

" He's *always* moving *everything*," said my wife " Every time I come out into the garden the plan is changed I never know where to look for things "

" And isn't that what the ladies do in the house ? " said Mr McGillivary " When a man wants his pipe or his slippers or a piece of string or his screwdriver where are they ? Moved ! "

I smiled on Mr McGillivary Not for nothing had we thrown together the companionable dart at the *Golden Ball* I looked towards the orchard

" Where would you put them, Mr McGillivary ? "

" In the orchard The ground is sweet under the apple trees, and when summer comes their skins will be bursting with sugar "

* * *

The Church, the Army, the Law, and Medicine are all in their way connected with death The cloth discusses it, the warrior arranges it, the solicitor is ready for it, the doctor delays it (or tries to do so) These lugubrious conclusions arose from my recent visits to the third of *these fell sergeants The man of law's touch* was so light His remarks were far removed from the forebodings of the post-Victorian revivalist He spoke of some far off divine event When the event happened, you, me, the client would be obviously performing a gracious act (gracefully), and he was armed at all points cap à pie to carry on the good work with all propriety How comforting a speculation Everything prepared for Nothing, or only very little, to go wrong

Part of the solicitor's finesse comes from good training, from those articles, not the thirty-nine, for which as a penurious father I have just paid so much, but part surely from the fact that the lawyer acts after life, and the parson, the colonel, the doctor during life When the Law is in action during life its mills grind as slowly as those of God, its results may be as uncertain or as foggy as the case of Jarndyce *v* Jarndyce

If our profession could be as futuristic as the family solicitor is, how different it would be Luckily I suspect for ourselves, we are continually being held up to the ransom of necessary decision, and some of us can shut our eyes like the fighting man guided by some higher command, or like the cleric call upon some vision which not all mortals can share with him The sword of Damocles hangs by its thread, in Lincoln's *Inn* it has already fallen For us there are minefields everywhere the lawyer in his bulldozer is engaged in a mopping- and chopping-up proceeding

* * *

Yesterday during my matutinal period of reflection, my eye lighted on the rhythmically stamped cylinder of "Government Property" by my side, and I fell to thinking of the wonderful effect that slight and insistent propaganda can have Of all the expensive apparatus owned by the State, this cheap roll is the most jealously labelled Is this the source of our nation's difficulties? How little does H M Government understand the psychology of advertisement, how poorly does its material and site compare with that of the meanest drug-house! It is causing us to lose the respect we should have for things not our own We are being conditioned to throw down the drain what Whitehall has marked as its own

It may be the concern of Dr Hill in his new office to deal with this, lest the products of Government action block our national waterways and sewage canals No doubt the Ministry of Health will suggest that a shilling charge be put on each dispensation Lucky numbers and a monthly draw for tax-free prizes might overcome opposition to this, while some will be hoping that the discovery of an imperforate roll will bring the rewards of an imperfect sheet of stamps

WEST OF SUEZ

The Healthman's Moane

Whan that a manne thinketh that his foode
Is full of dirt and maybe is not goode,
Or mayhap feeleth that a piece of meat
Is froght with danger unto him that eat,
Or if it seemeth that a dung or spitt
Be full of Microbes lurking to transmit
The seeds of evil stynking of disease,
Whether it come from home or overseas,
Or if perchance 'twere that a mouse or ratte
A miller s flour or grain sacks has been atte,
There is a way vouchsafed whereby hee
May bring the noxious thing along to mee
It must in sooth be carried straightaway
For urgent matters can brook no delay,
Therefore do I affix to it a tabbe
And bear it instantly unto the Labbe—
A mean and sorry place of no great wealth
But natholess a proppe of public health
Wherein men using alchemy and smell
Can tell us whether bodeth ill or well
Each thing pertaining to the nation's meat
And drink withal, a veritable feat
The Labbe's kindly folk will do their best
To find if therein harbour plague or pest

When Healthmen find that they can get the juice
They put the Labbe to quite a bit of use
Needs must they get the wherewithal to go
But now the edict sayeth nay not so
A most disastrous tragedye indeed
Withholding from him what he sorely need
But unto such enactments must one bow
By using only what the law allow
Where Healthman s duty lieth in a towne
His channels may not be so greatly downe
But when amid the hills his places lie
In sooth can he but stand aside and sigh
Meseemeth it accordant to reasoune
The country Healthman is a sorry loone
For lo perforce he draweth in his horne
Trulye he wisheth he had never been borne
For eke withal the Healthman shall survey
The countryside from whence he draweth paye
And men in his employ must cart ye mucke
And garbage from men s houses in a trucke
Or else it shall be piled mountains high
And men will say it reacheth to the sky
The precious fluid must be used for thatte
To ask aught else is talking through a hatte
Behoves a man to put an utter bar
On milk or water carried from afar
What can be left till later must be stoppe
Affairs of health perforce must show a droppe

Letters to the Editor

NEONATAL COLD INJURY

SIR,—Dr Mann and Dr Elliott are to be congratulated upon their clear description (Feb 2) of what they have elected to call "neonatal cold injury" The term has the advantage of pointing to the most important single ætiological factor—chilling—while embracing a clinical picture which to the minds of many extends from an apparently uncomplicated hypothermia to an irreversible sclerema

I am glad that the authors mention that factors other than cold may help to precipitate the condition In some full-term infants who show this picture it is difficult to accept exposure as the most important operative factor I have seen two babies recently who illustrate this point

A male infant of 6 lb 1 oz birth-weight was born spontaneously by the breech His dissimilar twin died on the first day of life The survivor was apparently well until the fifth day, when he was noted to feed poorly and to feel cold He was red and had pitting œdema and a rectal temperature of 91°F He was transferred to the premature room where his temperature rose to 97°F within twelve hours, and without further treatment his temperature became stable within normal limits in a few days

The second patient, a boy of 6 lb 10 oz birth weight, was an assisted frank breech birth No abnormality was noted until the eighth day when he became lethargic, unwilling to feed, cold, and erythematous His rectal temperature was found to be 91°F Again recovery was rapid on his being transferred to the premature room

Both infants were born in the Simpson Memorial Maternity Pavilion and became hypothermic in a nursery the temperature of which was maintained by thermostatic control at 70°F. All other infants in the nursery were maintaining normal temperatures on each occasion The severest rigours to which they had been exposed amounted to brief periods of partial exposure during changing and weighing These can hardly be compared to the conditions prevailing in a new and inadequately heated prefabricated house in a snowstorm I have little doubt that the temperatures of these two infants would have fallen further had preventive action not been taken

There would appear to be in some newborn infants a deficiency of heat regulation because of which hypothermia may occur even under good conditions Obviously the cold injury will be more severe if the environmental temperature surrounding such babies is low or if the infant's condition is not quickly appreciated and rectified. There would appear to be some factor other than prematurity, infection, or cerebral birth injury responsible for this central derangement

I have treated this condition by short wave diathermy in a small series over the past two years with considerable success The response of laboratory animals rendered moribund by chilling and of hypothermic, not sclerematous, infants has been dramatic The treatment was devised primarily for the treatment of sclerema, but I have not as yet had the opportunity of using it in this condition Although I appreciate the hazards of increasing the metabolic rate in the presence of asphyxia, it has appeared to me a logical form of treatment in some such cases The coexistence of infection of the respiratory tract and elsewhere is common The hypothermic infant is less capable of dealing with invading organisms than the normal baby The growth of the bacterial invaders, however, is not greatly influenced by the fall in body-temperature Changes in the subcutaneous fat of the thorax add to the respiratory embarrassment The duration of survival of the 8 fatal cases in the series of 14 infants described by Mann and Elliott varied from 7 to 100 hours with an average of 40 hours For the reasons I favour radio-frequency rewarming and the simultaneous careful use of oxygen

The technique which has been evolved by Miss Sheila Cameron, M C S P, and myself is still experimental, and through-and-through heating by short wave diathermy is not advocated for general use Severe local burning may occur in the presence of wetness or if the coil is improperly spaced I have no doubt that a safe technique is now possible, and a full description of it and of the results obtained will be published later

Department of Child Life and Health, University of Edinburgh JAMES W FARQUHAR

HYPERTENSION PRESYMPTOMATIC DIAGNOSIS AND TREATMENT

SIR,—Many of us share Professor Sanjivi's interest in the early and uncomplicated phase of essential hypertension (Feb 2), and are concerned to know at what stage in the evolution of the syndrome it is right to intervene with a potent hypotensive drug The trouble with Dr Sanjivi's contribution to this problem is that, by the evidence of his representative case, his patients are not hypertensive in the proper sense of having an established high diastolic pressure They are " diastolic reactors "—people whose pressure may be found casually raised but can fall within normal limits in nice circumstances and during sleep In any case, an emotional reactivity of the diastolic pressure is a phenomenon of hypertension at all stages

In my sort of psychosomatic interviewing,[1] with the patient at rest on a comfortable couch and showing no manifest anxiety, the average diastolic swing has been 25 mm Hg during the discussion of his life situation, and swings of 45 mm are not uncommon The casual reading gives no indication of the potential seriousness or otherwise of this liability, because it may lie anywhere along the range according to circumstance In particular it is unreliable as a base line for assessing the effect of treatment

I do not believe that Dr Sanjivi has done more than demonstrate the fall in pressure as recorded by a particular doctor when he has established a good therapeutic relationship with a diastolic reactor That the pressure stays satisfactory when the reserpine is stopped is proof of this

I do not take issue with the use of reserpine when the hypertensive condition is severe, but I am sure that the way Dr Sanjivi proposes is unwise Firstly, if relief from worrying is a rationale, it must be said that in psychiatric practice reserpine has not proved itself better than amylobarbitone sodium[2] Secondly, it is not innocuous Smirk and McQueen[3] report that half their hypertensive patients complained of mild symptoms such as lassitude and some disturbance of sleep by nightmares, and a tenth had significant depression In general, the depression may demand psychiatric measures in 5–20% of cases, and suicide is not uncommon In our state of ignorance about the prognosis for a patient with a casual diastolic reading of 105 mm Hg, 115, or, for that matter, 125, in the absence of complications, I do not see that we shall help by introducing a definite hazard of depression or impulsive suicide

Hypertension is probably not a disease until it begets complications, and I think that a man may be a diastolic reactor throughout life without running into any more circulatory trouble than a normotensive person We cannot evaluate the " late results of early treatment " until we know the late results of being a youthful diastolic reactor in the absence of treatment In the meantime, unlike Dr Sanjivi, I believe we should regard diastolic reactivity as a benign process—or shall I say only a little less benign than life itself, which is rather apt to end in cardiovascular disease It is compatible with a normal life span and with normal activities The patient needs to be protected from the anxieties of his doctor about the ultimate prognosis A worried preoccupation with blood pressure readings, the premature imposing of restrictions, and the giving of drugs are potent sources of disabling anxiety symptoms

Except in the accelerated phase, headaches do not call for hypotensive measures They should be treated on their merits as tension or conversion symptoms Better than succumbing to the blandishments of the drug houses and writing a prescription is a little sympathetic listening to the social, occupational, and family troubles that may be responsible for hypertensive episodes and outbreaks of anxiety and depression The hypertension is best kept in the background, watched with masterly inactivity (or " hands folded ") for the approach of complications, whilst the patient is treated as a person who from time to time gets into emotional difficulties with people in his environment

Cranbrook, Kent JOHN HAMBLING

SIR,—Dr Sanjivi has discovered the fallacy of a name—" benign hypertension ", he rightly states that it often kills We all know that Malignant, benign, essential, renal hypertension are all variants of " hypertensive disease "

There is no need to rail against this terminology It is not meant to lead anywhere, and cannot therefore mislead Mr Smith may be a woodworker, pernicious anæmia is a harmless disease, and my grandmother may develop athlete's foot—no need to wax indignant, we all know what is meant Names and labels are useful, they are not substitutes for descriptions even where they sound descriptive

Dr Sanjivi having unmasked the devil that lurks behind " benign hypertension " should go one further and exorcise the gremlin that lives in his sphygmomanometer Whenever this instrument records above 150 mm systolic and 95 mm diastolic this gremlin whispers " disease " into the doctor's ear, and leads doctor and patient into the pharmacological wilderness Yet, nine times out of ten he is dealing with a harmless elevation of blood-pressure that is ephemeral, truly benign, and not " disease "

Sir, a misunderstood sphygmomanometer reading can be as misleading as a name taken at its face value Do not let us be misled by this facile but fallible gadget into the large-scale study of treatment of mostly healthy people Let us first find out who needs treatment ! What we need is not eleven cases treated over 11 or even 21 months We need ten times eleven cases, observed without meddlesome treatment over twice 11 years, with records not only of blood pressures but of urinary, fundal, biochemical, radiological, and electrocardiographic findings, set against the subject's heredity, constitution, environment, and occupation Out of that study might—or might not—come a simple sign that would indicate when " moderately elevated blood pressure " is the precursor of " hypertensive disease "

We would then still have to find out whether hypertensive disease is as amenable to treatment as the ubiquitous patient with a " headache and a tired feeling at the end of the day " and a blood pressure of 168/106

In the absence so far of such a discriminating sign it is our first duty not to submit healthy people to " certain simple restrictions of activity [what activity, and why ?] and diet " We must still investigate adequately those patients with increased blood pressure, particularly if their symptoms are more specific than " headache and tiredness ", we must evaluate our findings, temper them with our judgment, treat the few, and spare the many

INTERACTION OF DEPOLARISING AND NON-DEPOLARISING RELAXANTS

Sir,—We regret that circumstances delayed our reply to the interesting letter of Dr Churchill-Davidson (Nov 10) In this communication he took exception to the use of the term "unexpectedly increased sensitivity to *d* tubocurarine" used in our previous letter

In an attempt to prove that our findings should not have been classified as "unexpected" he cites observations on the changing response evoked by repeated doses of C10 in certain mammals[1] and by a single dose of the same compound in myasthenics[2] These observations were not unknown to us and as a matter of fact were links in the chain of thought leading to the present understanding of the mode of action of depolarising muscle relaxants These observations, however, do not make our findings obvious, and thereby unworthy of reporting, as is implied by Dr Churchill Davidson

Whether an observation is expected or unexpected depends on previous experience and mental outlook. We do not wish to argue this point, but would like to emphasise that, from observations on the changing character of the block caused by depolarising drugs in certain mammals, the differences observed in the type of block caused by these agents in myasthenic individuals, and the fact that neuromuscular block produced by prolonged administration of these agents can occasionally be reversed in man by anticholinesterases, it does not necessarily follow that increased sensitivity to non depolarising muscle relaxants should be encountered after prolonged administration of depolarising substances in all human subjects tested

If Dr Churchill Davidson, or anybody else, had formulated the hypothesis that "prolonged administration of depolarising drugs makes the endplate more resistant to depolarisation," *then indeed the findings of Dr Brennan*[3] *and those of ourselves* could not have been classified as "unexpected" Such a hypothesis, however, as far as we know, has never been suggested, and only after the findings of Thesleff,[4] Brennan,[3] and ourselves became available did we feel justified in advancing the above hypothesis

Additional experimental evidence obtained with the sciatic gastrocnemius preparation of dogs and cats[5] and further clinical observation in man confirmed our assumption that prolonged administration of depolarising relaxants (e g, suxamethonium and decamethonium) produces gradually increasing resistance of the endplate to depolarisation In man, this increasing resistance may first be manifested by the need to increase the dose of depolarising relaxant to maintain a myoneural block of unchanged intensity At this stage, the block is presumably still a depolarisation block, because it is intensified by anticholinesterases Increased sensitivity to non depolarising relaxants, however, is already evident at this time In certain human subjects, but by no means in all, the resistance of the endplate to depolarisation can increase further, and in these cases the original depolarisation block can change to a non depolarisation block reversible by anticholinesterases

The rate of change in the sensitivity of the endplate to depolarisation varies, not only with the species investigated, but also with individuals of the same species and different muscles of the same individual It is fortunate that in most instances acetylcholine, the "physiological transmitter" is still capable of depolarising the endplate, and thereby restituting myoneural transmission, at times when suxamethonium or decamethonium are no longer capable of producing depolarisation

While we have the pen in hand, we would like to take exception to the use of the term "dual" block. The word "dual," as commonly used, implies two different actions occurring simultaneously (e g, the nicotinic and muscarinic effect of acetylcholine) It is now evident that the type of block previously classified as "dual" is caused by progressive changes in the properties of the endplate These changes can occur with varying speeds in different species In view of the gradual change in the properties of the endplate and the nature of the block the term "biphasic" (originally suggested by Jenden et al.[6]) or "multiphasic" block would depict the events at the endplate more truly and would be less likely to lead to misunderstanding of the basic principle involved

HOME CARE FOR SICK CHILDREN

Sir,—With reference to last week's article by Dr Lightwood and his colleagues, I must correct a wrong impression created by the statement that in the home-nursing unit set up in Rotherham in 1948 with which I was associated, there is no direct connection with the hospital services In fact great stress has always been laid on cooperation with the hospital services, and the home nurses used in the unit attend hospital for a brief refresher course before commencing work with the unit This point is shown quite clearly in the filmstrip made by Camera Talks showing the work of the unit

J Adrian Gillet

Dagenham Essex   Medical officer of health

"DOCTOR"

Sir,—It was with interest and amusement that I read Dr Graham's enlightening article (Feb 2) It is only to be regretted that the article was written by an F R C P and not an F.R C S—which would have perhaps added weight to the wise suggestion put forward

As an overseas doctor of medicine and a qualified surgeon, I am really struck by the importance surgeons attach to the title Mister This in itself may not be so important, and indeed may simply be classified as one of those "traditional" things that linger on and, in a way, add originality to the British way of life But does it not become ridiculous when the infection spreads downwards through all the layers of medical personnel ? A houseman insists on being called, or is called, Mister during his six months in the surgical wards, then he changes over to the medical firm and is addressed as Doctor, and perhaps does not very well know what to be called during his gynæcological training ! (Likewise, the ward sister, on obtaining an administrative appointment, insists on being addressed as "Miss")

These are amusing rather than fundamental anomalies But what is more serious is the use of the term Doctor in a derogatory way How often has a surgeon rebuked his houseman with that particularly stinging accent on the last word of "I told you to hold that retractor, Doctor" ! I know of at least one sister who addresses the surgeon as Doctor when she is cross with him, and as Sir or Mister when he is in favour with her

As Dr Graham says, the practice causes a good deal of confusion among the public, and who has not known the patient who has shyly asked us whether we should be called Doctor or Mister ? Worse still, surgeons have known the inconvenience of being reduced to a doctor's level during travel abroad, where all medical men are called Doctor

In the scale of medical degrees, strictly speaking only he who has obtained the M D degree of a university can be called "Doctor" But the general public tend to address all medical men as doctors, and the term can perfectly well be retained for this purpose, without harm to anybody If one had to search for logic, it is all surgeons *and* physicians who have not obtained their M D who should be called Mister leaving the Doctor privilege to those who have their doctorate

Perhaps the best solution is to take the public as the final arbiter for them a doctor is he who practises as a qualified and registered medical man, whether he is called upon to treat Johnny's measles, to repair mother's prolapse, or to remove grandpa's prostate

Southall Middlesex.   C Swan

Sir,—One finds nurses and other medical personnel refusing to address anyone with a doctor's degree as "Doctor," unless he has a medical qualification this happens not only in speech, but also in writing and reasons I favour radio-frequency rewarming and the simultaneous careful use of oxygen

The technique which has been evolved by Miss Sheila Cameron, M C S P, and myself is still experimental, and through-and-through heating by short wave diathermy is not advocated for general use Severe local burning may occur in the presence of wetness or if the coil is improperly spaced I have no doubt that a safe technique is now possible, and a full description of it and of the results obtained will be published later

TOWARDS PREVENTING SUICIDE

SIR,—The article by Dr Parnell and Dr Skottowe (Jan 26) and your annotation thereon are valuable in drawing the attention both of the medical profession and the public to the gravity of the problem I disagree, however, with one conclusion in your articles—that treatment should be admission to a mental hospital

In 1954 of 50 cases of attempted suicide admitted to the general hospitals of this group only 3 required subsequent admission to a mental hospital These figures were published with a suggested scheme of preventive action[1] to counteract some of this annual carnage

With the overcrowding of mental hospitals, many more psychiatrists should be included on the staffs of general hospitals, without them of necessity being attached, as now, to mental hospitals This is unlikely to come to pass as long as regional boards receive most of their advice on mental health policies from medical superintendents of mental hospitals, whose primary concern is naturally for the mental hospitals

Provided adequate psychiatric facilities are available at the general hospital, very few potential suicides need admission to a mental hospital The cooperation between the medical, anæsthetic, and psychiatric departments at this general hospital is such that three members of the resident medical staff and one clinical assistant general practitioner administer electroconvulsion therapy and apply other psychiatric therapeutic techniques to inpatients and outpatients under the direction of a consultant psychiatrist, and a number of beds are available in the medical wards for psychiatric cases

I agree that preventive social psychiatry holds the key, and it may well be that the public health services will in the future examine all school children psychologically, as they now do physically, and that adults may be similarly screened periodically

RADIOACTIVE VITAMIN B_{12} IN THE DIAGNOSIS OF NEUROLOGICAL DISORDERS

SIR,—In their interesting paper last week Dr Berlyne and his colleagues rightly stress the value of absorption tests with radioactive B_{12} for distinguishing non anæmic patients with subacute combined degeneration from patients with other cord and nerve lesions It should, however, be emphasised that, valuable as these tests are particularly in the treated patient, they give only indirect evidence of vitamin B_{12} deficiency

Neurological lesions due to vitamin B_{12} deficiency may occur in "vegans" who are able to absorb vitamin B_{12} normally,[2] and patients without vitamin B_{12} deficiency may be unable to absorb normal amounts of the vitamin[3] For these reasons direct evidence of deficiency of vitamin B_{12} is desirable before making so important a diagnosis as subacute combined degeneration of the cord In non anæmic patients this can be obtained only by measuring the concentration of vitamin B_{12} in the serum Patients with subacute combined degeneration of the cord have very low serum vitamin B_{12} concentrations whereas patients with other neurological lesions have either normal or only slightly subnormal concentrations of vitamin B_{12} in the serum[4]

Of the methods available for studying absorption of vitamin B_{12}, Dr Berlyne and his colleagues selected the Schilling test as the most convenient It should, however, be remembered that this method has two minor disadvantages Firstly, its accuracy is entirely dependent on a patient's ability to collect the urine passed during a 24 hour period This may be difficult, particularly in confused or incontinent patients or in elderly females Secondly, the urinary excretion of radioactive vitamin B_{12} is considerably reduced in patients with renal disease,[5] so that the results of the Schilling test may be abnormal even though the intestinal absorption of vitamin B_{12} is normal[6]

BIRTHDAYS OF SPASTICS

SIR,—Recently when reviewing spastics of school age, quite accidentally I noticed that their months of birth were not evenly distributed throughout the year Of the 62 spastics reviewed only 10 were born in the four months December to March The largest numbers were born in the period June to August (25) This difference hardly seems to be a matter of chance

There seem to be two possible causes for this uneven distribution Do spastics who are born in the cold months of the year tend to die at a very early age? In this respect the article by Dr Mann and Dr Elliott (Feb 2) might be of interest, particularly as spastic children are known to be sensitive to changes of temperature If in fact there are fewer actual births of spastics during the period December to March, one may have to think in terms of infections of the mother during pregnancy

It would be interesting to know, from those who devote much of their time to the care of spastics, whether this observation is confirmed

PNEUMOTHORAX IN TRACHEOTOMY

SIR,—I was interested in Dr McMath's report[7] of pneumothorax complicating tracheotomy in a case of laryngo tracheo-bronchitis I was involved in the supervision of two cases of this nature, both patients died, and even at necropsy no tear in the parietal or visceral pleura could be seen

CASE 1—An infant, aged 11 months, who had been "croupy" for 5 days, became much worse despite treatment Rib retraction increased, the pulse rate rose to 160 per minute and he was pale and becoming restless

Accordingly tracheotomy was performed The tracheotomy tube was finally inserted after a little difficulty, but thereafter his condition did not seem to improve He was cyanosed and his ribs were still retracted An hour later examination suggested left sided pneumothorax His left chest was needled at once, but he died

Necropsy showed acute laryngo tracheo bronchitis with left sided pneumothorax and massive collapse of the left lung, subcutaneous emphysema around the wound in the neck and also a little in the mediastinum, no rupture of the pleura, and grossly enlarged thymus (32 g) which microscopically was normal

CASE 2—An infant, aged $6^1/_2$ months had been "croupy" for 24 hours He had slight indrawing of the ribs, and did not improve with treatment in a steam tent The following morning his pulse rate was 140 per minute, his colour was good but he was obviously exhausted and his ribs were still moderately retracted A tracheotomy was performed, but he collapsed about 15 minutes later, became cyanosed and died

Necropsy showed the anterior mediastinum ballooned with air, subcutaneous emphysema extending throughout the such people will not be corrected The public's use of Doctor is as a vulgarism they cannot be bothered to say *general practitioner* or *medical attendant*

THE PLIGHT OF HOSPITAL PHARMACY

SIR,—All that Sir Hugh Linstead says (Feb 2) applies with equal force to physiotherapists, and indeed all of the so called auxiliaries It is surely time that a complete review was made of salaries and conditions of these grades, and a degree of reality introduced

Sudbury, Suffolk DAVID WHITE

SEPSIS IN THE NEWBORN

SIR,—The purpose of the investigation reported in the article by one of us,[1] to which your annotation of Jan 26 refers, was a very limited one to find out if, in a maternity hospital, a relatively simple technique for the routine care of the skin of the newborn could safely be substituted, during the first week or two of life, for the traditional technique involving regular bathing We found no increase in the incidence of various skin troubles (*including staphylococcal lesions*) *among the babies* cared for by the simpler method

Your annotation was mainly devoted to making two suggestions for remedying the fact that the investigation was " not conclusive as far as sepsis is concerned," and we would welcome the opportunity to make a brief reply to these suggestions

While it is undeniably true that, mathematically speaking, " an investigation lasting two years would have been more conclusive " (always provided that the one observer had had the stamina to see it through), we do not think that any corresponding practical advantage will inevitably result from such a prolongation of an investigation of this kind We certainly would not expect to encounter the acid test you so confidently predicted—" a flare-up with widespread infection and severe lesions " During the period of the past ten years, for which we have accurate day-to day records of the incidence of skin sepsis in the Princess Mary Maternity Hospital, there has been a good deal of unexplained fluctuation from time to time (no doubt partly attributable to unconscious differences between the standards of different observers) but there has been only one episode which might be described as a " flare up " In May, 1951, when a change was made in the technique for the routine care of the cord, there was a rapid rise in the incidence of skin sepsis so that in June 35% of the babies in the hospital developed one or more pustules during their stay (fortunately there were no " severe lesions ") The situation was promptly brought under control again by a further change in the technique for the care of the cord Past experience, therefore, would lead us to be wary of the *apparently innocent* change in technique which may lead to unfortunate and unforeseen consequences on a large scale But it would not lead us to expect " at least one flare up " every two years

It is also undeniably true that, as compared with the *follow up period* which we relied upon (the duration of the babies' stay in hospital), " a follow up of four months might have revealed some sepsis later " But even if there is any causal connection between the serious visceral or bony lesions which may appear later, and " *the relatively small skin lesion appearing* in the first week," which has healed rapidly, we would not have expected to find a different incidence of these later lesions in two groups of babies which had shown the same incidence of the initial skin lesions Furthermore, it is *one of the advantages of working in a provincial centre* that one should be able to obtain an accurate idea of the true incidence of such serious lesions With regard to staphylococcal osteitis, for instance, we know that during the past eight years only two babies under the age of 4 months, who had been born in the Princess Mary Maternity Hospital, have been *admitted to the pediatric* wards in the region for treatment This figure gives an idea of the meagre reward which we would expect to be gained by a four-month follow-up of all the babies discharged from the hospital during a period of two years

In short, we would like to suggest that the planning of an investigation of this kind ought to be based upon the solid foundation of a knowledge of the natural history of the conditions which it is proposed to study, in the particular institution concerned (rather than upon generalisations which may be true of some institutions, but not of others) and that it may be wiser to budget for a result which is " not conclusive " (but which will tell one what one wants to know), rather than to strive after some arbitrary standard of conclusiveness, and risk finding oneself *to be engaged in the laborious pursuit* of a will-o'-the-wisp

THE Rh BLOOD-GROUPS

SIR,—I was pleased to read that Dr Nicholas (Jan 19) acknowledges that, irrespective of nomenclature, the use of " most likely genotypes " leads to paradoxes The point is that the paradox was introduced into blood-group literature by the CDE protagonists, as can be seen by consulting the book of Race and Sanger In my own writings I have always been scrupulous in distinguishing phenotypes from genotypes, and so have all other workers who thoroughly understand the subject, and who therefore avoid the CDE notations I trust that Dr Nicholas's letter means that he intends to persuade Dr Race and other CDE protagonists to abandon the use of " most likely genotypes " This will be the first *step in clearing up their confusion, and then* there are some two dozen additional paradoxes for which CDE protagonists are responsible,[1] which await Dr. Nicholas's attention

Your leading article of July 21 last year stated that the CDE notations have " given every satisfaction, being easy to remember and understand " This statement is based on a misconception, since when workers use the CDE notations it is *because* they *do not* understand the subject Those who thoroughly understand Rh-Hr serology and genetics have no difficulty with the correct Rh-Hr nomenclature, because this merely translates facts they already know into symbols Your editorial also states that " it seems unlikely that outside the United States pathologists and others will wish to change over from the Fisher-Race to the Wiener nomenclature—a change which would involve much effort " This statement is also incorrect, because almost all those who are now using the CDE *notations* are also using the co called " shorthand " notations What is entailed therefore is not to learn something new, but to discard something old which has been shown to be incorrect All intelligent workers will welcome such a simplification

In a recent article,[2] it is pointed out that the medico legal expert is expected to master all intricacies of Rh-Hr serology and genetics If such an expert uses the CDE notations, this demonstrates his *lack of* understanding of the subject, and may be used *by a* lawyer to challenge his qualifications The argument that the use of these symbols is needed to simplify the matter for the judge and jury is fallacious, because the competent

TOWARDS PREVENTING SUICIDE

Sir,—The article by Dr Parnell and Dr Skottowe (Jan 26) and your annotation thereon are valuable in drawing the attention both of the medical profession and the public to the gravity of the problem I disagree, however, with one conclusion in your articles—that treatment should be admission to a mental hospital

In 1954 of 50 cases of attempted suicide admitted to the general hospitals of this group only 3 required subsequent admission to a mental hospital These figures were published with a suggested scheme of preventive action[1] to counteract some of this annual carnage

With the overcrowding of mental hospitals, many more psychiatrists should be included on the staffs of general hospitals, without them of necessity being attached, as now, to mental hospitals This is unlikely to come to pass as long as regional boards receive most of their advice on mental health policies from medical superintendents of mental hospitals, whose primary concern is naturally for the mental hospitals

Provided adequate psychiatric facilities are available at the general hospital, very few potential suicides need admission to a mental hospital The cooperation between the medical, anæsthetic, and psychiatric departments at this general hospital is such that three members of the resident medical staff and one clinical assistant general practitioner administer electroconvulsion therapy and apply other psychiatric therapeutic techniques to inpatients and outpatients under the direction of a consultant psychiatrist, and a number of beds are available in the medical wards for psychiatric cases

I agree that preventive social psychiatry holds the key, and it may well be that the public health services will in the future examine all school children psychologically, as they now do physically, and that adults may be similarly screened periodically

RADIOACTIVE VITAMIN B_{12} IN THE DIAGNOSIS OF NEUROLOGICAL DISORDERS

Sir,—In their interesting paper last week Dr Berlyne and his colleagues rightly stress the value of absorption tests with radioactive B_{12} for distinguishing non anæmic patients with subacute combined degeneration from patients with other cord and nerve lesions It should, however, be emphasised that, valuable as these tests are, particularly in the treated patient, they give only indirect evidence of vitamin-B_{12} deficiency

Neurological lesions due to vitamin B_{12} deficiency may occur in "vegans" who are able to absorb vitamin B_{12} normally,[2] and patients without vitamin B_{12} deficiency may be unable to absorb normal amounts of the vitamin[3] For these reasons direct evidence of deficiency of vitamin B_{12} is desirable before making so important a diagnosis as subacute combined degeneration of the cord In non anæmic patients this can be obtained only by measuring the concentration of vitamin B_{12} in the serum Patients with subacute combined degeneration of the cord have very low serum vitamin-B_{12} concentrations, whereas patients with other neurological lesions have either normal or only slightly subnormal concentrations of vitamin B_{12} in the serum[4]

Of the methods available for studying absorption of vitamin B_{12}, Dr Berlyne and his colleagues selected the Schilling test as the most convenient It should, however, be remembered that this method has two minor disadvantages Firstly, its accuracy is entirely dependent on a patient's ability to collect the urine passed during a 24 hour period This may be difficult, particularly in confused or incontinent patients or in elderly females Secondly, the urinary excretion of radioactive vitamin B_{12} is considerably reduced in patients with renal disease,[5] so that the results of the Schilling test may be abnormal even though the intestinal absorption of vitamin B_{12} is normal[6]

BIRTHDAYS OF SPASTICS

Sir,—Recently when reviewing spastics of school age, quite accidentally I noticed that their months of birth were not evenly distributed throughout the year Of the 62 spastics reviewed only 10 were born in the four months December to March The largest numbers were born in the period June to August (25) This difference hardly seems to be a matter of chance

There seem to be two possible causes for this uneven distribution Do spastics who are born in the cold months of the year tend to die at a very early age? In this respect the article by Dr Mann and Dr Elliott (Feb 2) might be of interest, particularly as spastic children are known to be sensitive to changes of temperature If in fact there are fewer actual births of spastics during the period December to March, one may have to think in terms of infections of the mother during pregnancy

It would be interesting to know, from those who devote much of their time to the care of spastics, whether this observation is confirmed

[7] McMath, W F T *Lancet* 1956 ii, 750

In these two cases the respiratory disorder had been present for some days, and it may be in such cases that the danger of pneumothorax is greatest Furthermore, a low tracheotomy was performed in both cases, and it is obviously easier for air to enter the cervical fascia and mediastinum with this low approach to the trachea

After opening the neck with the tracheotomy incision the tube must be inserted quickly, as the inspiratory efforts are still great until the trachea is opened Furthermore, the tube must be secured firmly, as if it slips out respiratory distress may begin and air be sucked in [3]

A MISSED FRACTURE

SIR,—I would like to believe that Dr Stone intended his letter (Feb 2) to be taken as a piece of sarcasm If this is indeed the teaching in our medical schools today there is every excuse for the diminishing esteem with which our profession appears to be regarded by the public As Dr Stone says, the public has a right to treatment, and that treatment should be the treatment of whole human beings—not of arms or legs or skulls or what you will An adequately complete examination is not so time consuming as Dr Stone seems to think Anything less deserves every stricture that is coming to it and can certainly be regarded as evidence of lack of proper professional care No doubt we all of us fall short of the ideal on occasion That should not prevent us from recognising and regretting a lapse in professional standards

Marlborough College,
Wilts　T A A HUNTER.

SHORTAGE OF RADIOGRAPHERS

SIR,—As one of the older radiographic workers, I should like to comment on Dr Illingworth's letter (Jan. 5)

Dr Illingworth states that it is wrong to assume that the present shortage of radiographers is primarily due to inadequate remuneration, and that the dissatisfaction is largely confined to the few male radiographers

In my own small circle I know of three young married male radiographers, all with children, who have found other work simply because they could not make ends meet on their salaries as senior workers I also know of two others who have emigrated for the same reason As regards new entrants to the profession, I know that prospective male students, and their parents, lose interest when informed of the salary scale Exception is taken not so much to the initial salary (although this is on a par with that of a hospital porter) as to the absence of career prospects

Dr Illingworth says that radiography is essentially a job for a girl I wonder why "essentially"? Is it simply because a girl can afford to work for a smaller salary than a man? I can think of no other reason Personally, I think a man is the better proposition in the long run—better because, provided that he earns enough to keep himself and his family in reasonable comfort, he usually stays in a job for life, whereas the majority of women forsake it for marriage

It is true that the modern radiographer does not need to possess the electro technical knowledge which was required by the radiographer of former days, but surely Dr Illingworth will admit that knowledge of other kinds is required? I have been in X ray work for over forty years, both as an engineer and as a radiographer, and I am still learning

The other things which Dr Illingworth mentions are mostly related to professional standards Radiographers have had to fight for what little place they have in t sun, and it is surely unreasonable to expect them reduce their professional standards because of a shorta of radiographers, especially since they themselves are no way to blame for the shortage Why should we op our doors to the illiterate—assuming, of course, that t illiterate could do our work? Radiographers are doi no more, no less, than other professional bodies do A professional bodies, without exception, partly in t furtherance and the protection of their own interes strive to maintain as high a standard as they possib can In a democratic society their right to do so is bo recognised and upheld

When Dr Illingworth ridicules the idea of a pre entr qualification in English, and thereby infers that it shoul be done away with, he is asking radiographers to u their professional throats The salaries of radiographe are determined by Whitley Council machinery, and th machinery is extremely sensitive to such things as pr entry qualifications and length of training Where wou we stand if we reduced our standards? Surely it mu be realised by all that prestige and status mean just much to a radiographer as they do to any oth professional person

Swansea Hospital　DONALD R GOULD

AMIPHENAZOLE

SIR,—If Dr Ballantine's findings with amiphenazol (Feb 2) can be confirmed in a large series of cases, w will have a drug of great value in the treatment intractable pain In a series of ambulatory patients wh have received oral amiphenazole and large doses analgesics, some of the claims made by McKeogh an Shaw [1] have not been confirmed, especially as regard reduction of vomiting, constipation, and respirator depression However, I have, as yet, found no evidenc of addiction in any of the patients, during periods treatment lasting from 2 to 27 weeks

The acid test of prevention of addiction would be th ability to reduce the dose of analgesics without with drawal symptoms, but since pain was mostly due t malignant disease this was rarely possible

Analgesics have been stopped entirely in 5 patients In 2 instances because of lack of benefit where severe pain was only intermittent and was of short duration, and in 3 patients where relief was obtained by nerve section or alcohol block Their daily dose of analgesics was as high as 54 mg levorphanol or 250 mg methadone with 120–300 mg amiphenazole, and no side effects were observed during the withdrawal period, which did not exceed one week Levorphanol and methadone were the only analgesics which proved to be consistently effective by the oral route

Vomiting, which is a major problem when large doses of potent analgesics are given by mouth, does not appear to have been reduced by amiphenazole Its occurrence is unpredictable, some patients will tolerate enormous doses while others cannot retain even the smallest dose Vomiting responds very well to cyclizine or chlorpromazine, but chlorpromazine intensifies the soporific effects of the analgesics [2]

In view of the apparent prevention of addiction to analgesics by amiphenazole, the drug has been given to a few patients with severe post herpetic neuralgia, and the results have been most gratifying

One elderly patient, who attempted to commit suicide because of pain, was started on 18 mg levorphanol with 100 mg amiphenazole daily about six months ago She voluntarily reduced this to 13 5 mg levorphanol and 80 mg amiphenazole during the first few weeks and has continued on the same régime since

In view of the report by Dr Ritchie Russell and his colleagues (Feb 2) this treatment may be better reserved as a temporary measure, combined with intensive local therapy Patients could be made more tolerant to active treatment, and the analgesics stopped when no longer needed

PRACTITIONER AND LOCAL AUTHORITY

SIR,—I do not wish to revive the lively correspondence under the title "Clinicosis," but your editorial (Feb 2) warrants some comment

In quoting from Ramage's paper on this subject you express the view that "general practitioners *could* become responsible for some local authority services" In the sense of "competent to," I would agree, and, as a teacher, stress that it is not sufficiently realised that the medical student of today is taught much in the preventive field which the general practitioner alone can put into effective use

However, you state, equally dogmatically, that "from the correspondence most doctors think they *should* do this work" What really are the motives for this? In discussing the "take over" of clinic services you state

> 'but it is unlikely to happen for a long time unless general practitioners are given some *financial reward* [italics are mine] for providing these extra services As things now are, and as Ramage's inquiry illustrates it is doubtful whether the present size of general practitioners' lists allows them time for anything but a gesture at preventive work"

Further comment is hardly necessary, except to say that many general practitioners do not realise that preventive work often takes more time than curative, although unlike the latter its effects are likely to be cumulative One wonders whether the general public, who pay all the bills, would be convinced that at the moment the general practitioner has more time than he needs for his curative work The prerequisite for the general practitioner doing real preventive work would be a reduction in his curative case load

Department of Preventive Medicine and
Public Health University of Leeds
C W DIXON

UNMARRIED PARENTHOOD

SIR,—Dr Comfort writes (Jan 26) 'the devotion of moral agencies to the prevention of coition has often eclipsed their anxiety over the tangible suffering unwise coition may cause"

As one who has had some experience of one of these 'moral agencies'—the Church of England Moral Welfare Council—I am astonished at Dr Comfort's allegation, since moral welfare workers and councils are only too terribly aware that the amount of time and effort spent of necessity in connection with unmarried mothers and their urgent material problems leaves far too little time for the general educational work so essential amongst young people and which they feel should really be a first priority

Dr Comfort's suggestion that "the obvious first step' to reduce the present tragic unhappiness of the unmarried mother is "general contraceptive education" would prove an encouragement to young people to indulge in premarital coition as an interesting experiment rather than, as happens at present, as an uncontrolled emotion—thereby debasing the act to a far lower level than that on which it usually takes place Moreover it may be doubted whether universal knowledge of methods of contraception *would* appreciably reduce the illegitimate birth-rate since a high proportion of putative fathers and a not inconsiderable proportion of unmarried mothers are perfectly well aware of contraceptive methods but owing to carelessness, laziness, and lack of self-control and moral fibre, they urge or permit coition with little or no thought of the possible consequence

It seems doubtful if the tragedy of unmarried motherhood can be lessened by any means other than education—not in contraceptive methods, but in the proper relationship and respect one sex should have for the other and in the encouragement of the ideal that coition should be the culmination of the expression of the love of two persons who have accepted each other as a partner for life

Dr Comfort's suggestion that "the attempted prevention of sexual behaviour in young people" is one of the aims of moral-welfare organisations is as ludicrous as it is untrue "Sexual behaviour" is natural to both adults and young people This is fully recognised by moral-welfare workers who encourage it to progress on the right lines progress such as this does not lead to extramarital coitus, but the wider dissemination of contraceptive methods amongst unmarried persons suggested by Dr Comfort would, as I have previously suggested, by no means prevent unmarried motherhood, it would, on the other hand, almost certainly lead to an unnatural experimentation in the act of coitus, which should from the moral, practical, and æsthetic point of view be reserved for the culminating act of courtship and marriage

E C CORDEAUX

SYRINGE CARRIER

SIR,—Dr Stark Murray (Feb 2) almost fully answers the criticism made by Dr McDonald and Mr Pirnie (Jan 26) of the syringe carrier which I described in your issue of Jan 12 He fails, however, to elaborate upon his statement that this syringe carrier is "unlikely to solve the problems of the anæsthetist"

Dr McDonald does not appear to have understood fully how this box works

The number of syringes and their variety are composed beforehand to suit the particular operating list with which it is intended to deal The box is then opened only long enough for one syringe to be extracted at a time The box is then closed The time taken to do this is less than that in which a surgeon removes a gown from a gown drum Would Dr McDonald therefore suggest that this method of sterilising gowns should be abandoned? The time taken to extract a syringe is about a fifth of the time taken to fill the syringe, carry it to the patient and inject its contents into a vein

Dr McDonald does not appear to appreciate that the anæsthetist, when handling sterile apparatus, wears cap and mask and washes his hands Unlike Dr McDonald I do not believe that there is any real risk of a dirty syringe being replaced in the box

At the moment I am carrying out a series of tests to establish whether the air in one of these boxes remains sterile from start to finish of an operating list

London, S W 3
L H LEHMAN

ERADICATION OF TUBERCULOSIS

SIR,—Dr J H Hudson's letter (Jan 12) stimulates me to reply to his point (c) He asserts that the director of a mass radiography unit has a statutory duty to notify pulmonary tuberculosis on the basis of X-ray examination alone May I say that such action, apart from the ethical considerations, would be clinically and administratively inadvisable, leading to false notifications and unnecessary anxiety to patients Surely pulmonary tuberculosis should not be diagnosed but only suspected on an initial film Infiltration and cavitation can be due to other causes besides the tubercle bacillus and if notification is to be made prematurely without clinical assessment of the patient and bacteriological examination of his sputum, the medical officer of health's notification register will become unreliable

The present-day chest service is established as a means of supplying accurate diagnosis and treatment of pulmonary disease I consider it would be a retrograde step if doctors reading X-ray films were to start notifying cases as tuberculous It would be reminiscent of the bad old days when tuberculosis was notified on the simple basis of a chronic cough

Newcastle upon Tyne H R THOMSON

TETRAETHYL LEAD POISONING

SIR,—Tetraethyl lead poisoning due to cleaning tanks is a disease that may affect seamen I can add to the four cases of Dr Boyd and his colleagues (Jan 26) that of a Polish sailor who was an inpatient in the Seamen's Hospital (under the care of Dr Alec Wingfield) from October to December, 1956

He had abdominal colicky pain, tightness in the chest, and vomiting His scleræ were slightly icteric, he had a hæmolytic anæmia (hæmoglobin 8 2 g per 100 ml, mean corpuscular fragility slightly decreased, reticulocytes 6%, active normoblastic marrow, serum bilirubin 2 mg per 100 ml), and 0 8% of his red cells showed the coarse punctate basophilia of lead poisoning Urinary lead excretion was 0 3 mg in 24 hours He said that the haze of rust in the atmosphere during scaling of the tank gave rise to cough with rusty sputum It was interesting to compare this seaman with a case of straightforward lead poisoning in an accumulator worker who happened to be in hospital at the same time this patient's complaint was also colicky abdominal pain (he had been *thought to have a perforated peptic ulcer*), but he *had* no anæmia and excreted no lead in the urine, though he showed characteristic coarse stippling of his red cells Both patients responded very definitely to therapy with intravenous *edathamil calcium disodium* ('*Versene*')

Devonport Laboratory,
Greenwich London G L ROBINSON

THREE CASES OF DYSURIA

SIR,—Dysuria is a symptom met by all of us daily The following three cases all presented with this complaint, and the final diagnosis was made only with some difficulty The patients were all young males

CASE 1—A boy, aged 3 years, a thin miserable child who was always unwell, was said to have dysuria and abdominal pain *There was no previous history of urinary symptoms*

He had a tender abdomen and pyrexia, but, as he always cried when approached, it was hard to say how much pain he was having His urine showed a cloud of albumin I *thought his pain was too severe to be due to urinary infection*, and I requested his admission to hospital as a possible acute abdomen

After admission, he was observed for 48 hours, and a precautionary *laparotomy was then performed* At the operation, at which a normal appendix was removed, it was noticed that the left kidney and ureter were enlarged Investigation showed a normal right kidney and a gross left *hydronephrosis* and mega ureter, which proved to be due to chronic pyelonephritis The kidney was removed, and the child is now very well indeed, cheerful and chubby, with rosy cheeks and a ready smile

CASE 2—*A youth of 19 complained of dysuria* Examination of his urine showed a cloud of albumin The abdomen was not tender and he was afebrile A tentative diagnosis of cystitis was made and he was given sulphonamides and potassium citrate Then began a series of bizarre symptoms, including jaundice which lasted 48 hours His temperature was normal by day, but rose in the evening to 100 or 101°F He was seen at home by a surgeon who advised admission

On admission his temperature was 100°F, he was now tender in the left iliac fossa, and his left kidney was palpable Next day jaundice reappeared and a physician thought that he had an obstructive infection of the kidney Intravenous pyelography showed a space occupying lesion of the lower pole of the left kidney On examination of the kidney after its removal this was found to be a clear cell carcinoma A year later he is very fit

CASE 3—Another boy, aged 17, who also complained of dysuria, was afebrile, and had no abdominal pain His urine contained albumin A tentative diagnosis of cystitis was made and he was treated with sulphonamides and potassium citrate Next day he had diarrhœa and nausea I wondered whether he had dysentery with superadded cystitis, or diarrhœa due to the treatment The question was answered next morning when he said that he had passed blood in his urine A sample sent to the laboratory was found to contain many tubercle bacilli He is now being treated for renal tuberculosis

Thus three of the major diseases of the kidney presented with the same symptom—dysuria Then followed a number of red herrings which diverted attention from the kidney

William Budd Health Centre,
Knowle, Bristol H I HOWARD

TREATMENT OF POST-HERPETIC NEURALGIA

SIR,—The successful treatment of post herpetic neuralgia by mechanical vibration, described by Dr Ritchie Russell and his colleagues (Feb 2), prompts me to report the following case of trigeminal neuralgia

A man, aged 51, developed a right trigeminal neuralgia in 1950, following a bilateral Caldwell Luc operation An alcohol injection of the gasserian ganglion in 1952 produced only temporary and minor relief of pain The pain became so intolerable that in July, 1954, the trigeminal nerve was divided in the posterior fossa This produced immediate relief of pain, but unfortunately after the operation left hemiplegia with right facial palsy developed Later the right cornea ulcerated and a tarsorraphy was necessary *The facial pain slowly returned, and though less severe, was still burning* He has not worked since the operation

The patient was admitted here in October, 1956, at the request of a neurosurgeon, as an intractable rehabilitation *problem At that time he was socially independent and could* walk short distances with the aid of one stick, he could not climb stairs or walk out of doors, dressing was difficult He had a typical left hemiplegia with some shoulder control although only flexion and abduction *to 90°* There was virtually no control over the elbow, wrist, or hand The left leg was spastic and weak, extended at hip and knee, and he had a dropped foot He was emotionally unstable On attempting any sustained effort he experienced paroxysmal pain which began in the right upper lip and spread rapidly over the whole right side of the face, it lasted 3–5 minutes, during which time he had to remain motionless, and it left an intolerable burning pain which lasted more than 30 minutes This pain was only moderately controlled by pethidine 100 mg *three to six* times per day, and was unaffected by sedatives or tranquillisers The limit of his exercise tolerance was 20 yards slow walking This made functional retraining or therapeutic exercise impossible

To help with his rehabilitation, procaine iontophoresis (2%, 4–5 milliamperes, 5 minutes daily), was given by a large electrode applied to the whole of the right face For the *following two hours it was possible to proceed* with vigorous exercises without a return of pain, and during this period drugs were unnecessary The iontophoresis was then given twice a day, and within a month he had made a good functional *recovery* from his hemiplegia He was able to walk well, with only minor spasticity (his dropped foot was controlled by a below knee calliper), and he had almost *normal* arm and hand function However, his pain remained severe

The patient was given a break for Christmas leave, and after a short remission the pain became so severe that he returned by ambulance, heavily sedated He complained that the pain was worse than before nerve section and was no longer controlled by pethidine The pain was brought on by any effort and by eating, and also occurred spontaneously He was seen again by the neurosurgeon who could offer no help other than the possibility of leucotomy

Knowing of the success achieved with mechanical vibration in postherpetic pains by *Ritchie Russell and his* co workers this was tried with a *hand operated* mechanical vibrator The patient applied it himself for 5 *minutes* every hour to the trigger areas Within 2 days he improved remarkably, *and* by 7 days *the only trigger spot remaining* was at the inner canthus of the eye, which was inaccessible to the head of the vibrator This area has now responded to sustained digital (self applied) pressure

For the past 3 weeks the patient has been virtually symptom free and can take exercise without pain. *For the* first time in years he is taking pleasure in work and play He has been provided with a mechanical vibrator to use at home

This case well illustrates the point made by Ritchie Russell and his colleagues—that local anæsthesia by procaine iontophoresis and mechanical vibration may be valuable in the treatment of intractable pain

PULLED ELBOW

Sir,—The clinical entity which Dr Salkind (Jan 26) describes is well known, and most of us have been taught to accept it as due to a subluxation of the head of the radius out of the annular ligament This belief, I think, is based on a false assumption which is implicit in Dr Salkind's account of the varying relationship in size of the radial head and neck The assumption is that the annular ligament is around the *neck* of the radius, whereas in fact it is around the *head* of the radius The annular ligament is attached in front to the anterior margin of the radial facet on the coronoid and behind to the posterior margin of the same facet The stability of the radial head within the annular ligament cannot, therefore, be influenced in any way by the relative size of the radial head to the neck

My views about Dr Salkind's interpretation of this clinical condition are further reinforced by my own experience that these cases spontaneously settle down in a few days irrespective of any form of treatment, manipulative or otherwise

REPAIR OF FEMORAL HERNIA

Sir,—I had the good fortune to be taught McEvedy's approach to femoral hernia by a surgical registrar at my last hospital

In Nigeria one has four or five hernias on an average operation list, and many are femoral Recently at the Civilian Hospital I saw two women with femoral hernias (in one case bilateral) about the size of a large grape fruit I used McEvedy's approach in both cases with utmost satisfaction Perhaps the only drawback to this method is the tendency to puckering of skin when the vertical incision is used

I was pleased to read the article by Dr Mouzas and Dr Diggory[1] and the letter from Mr Reay-Young[2] I also purchased a recent large textbook of operative surgery, but could find no description of, or even reference to, McEvedy's approach

NEURONE SELECTION IN RELIEF OF PAIN

Sir,—I should like to call attention to the work of Dr Martonfy and Dr Balta[3] in the neurological department of this hospital We are using 10 ml of an aqueous solution of phenol (0 5%) injected through the first or second sacral foramen in all forms of sciatica, in herpes zoster, and in cancerous intractable pain The technique is that described by Bonica[4]

The principal difference between our method and that of Dr Maher (Jan 5) is that by our method the phenol diffuses into the perineural tissue, whereas Dr Maher injects it directly into the cerebrospinal fluid or the epidural dural tissue Our method has given very good results in 450 cases of sciatica and 54 of herpes zoster As a rule a single injection sufficed to relieve pain and allowed the patient to move and walk with ease The injection had often to be repeated in a day or two, but if as many as 3 injections were found insufficient the treatment was abandoned About 15–20% of our patients proved to be refractory

I have observed no disabling symptoms such as incontinence, and since the patients who were relieved have remained free from pain throughout the time of observation (one to two years) I have no hesitation in recommending this method for sciatica and herpes zoster

DANGEROUS CONTAMINANTS IN STORED BLOOD

Sir,—I too am greatly relieved that Dr Discombe (Feb 2) agrees that the use of blood that has been tapped (under approved conditions) may be safely used more than 24 hours after the tapping

The scanty evidence available suggests that contaminants in blood in sufficient strength to be dangerous are exceedingly rare, and that they are in the bottle or cap before the blood is collected, as in Dr McEntegart's cases,[1] and are not introduced by tapping the bottle under approved conditions This somewhat dogmatic assertion is based on perhaps uncertain, but to my mind convincing, evidence, for in those regions where pilot tubes are not supplied very many bottles must have been tapped and used more than 24 hours after tapping there is no record of blood contaminated in this way causing death

Dr Discombe asks how many patients I have saved from contaminated blood by the film technique during the short time the technique has been in use no contaminated bottles have been found If, however, antespective action had been taken, and the blood-film examined before rather than after the blood had been given, the two patients recorded by Dr McEntegart might have survived The same applies to other patients who have died from infected blood[2 3] There are probably yet others, as not all deaths due to transfusion are recorded, and in some cases in which contaminated blood has been given the cause of death may have been missed

If I had to prepare blood for a member of my family I would certainly examine a stained film I would not worry if the bottle had been tapped previously by a trained worker in whom I had confidence and who had all facilities and if it had been properly refrigerated under continuous laboratory control I would never use a bottle that had been handled by a careless clinician

AN AMERICAN IN BRITAIN

Sir,—It may be of interest to summarise my experience as an American Air Force physician during the past two years in Britain

At our station, which has roughly 3000 troops and 500 dependants, we see many hundreds of 'acute sore throats" In each case a throat-swab is cultured and generally no antibiotic is given unless a Lancefield group A organism is found We have found such an organism in only 26 cases in two years We have had no cases of rheumatic fever or of acute nephritis Standard treatment is one shot of 'Bicillin' (benzathine penicillin)

At our well baby clinic we see children roughly five times before the age of 3 years, and we try to apply a tuberculin skin test yearly We have found 4 positive reactors in two years, and these children (aged 4 years or less) are all being treated with isoniazid Progressive primary tuberculosis or other complication has not developed in any of them

We have had no cases of chilblains or similar cutaneous disorder, but many have reported skin complaints

---

[1] McEntegart M G *Lancet* 1956 ii, 909

[2] *Brit med J* 1952, i 1036

[3] *Ibid* 1954 ii 934

(dryness, scaling, pruritus) apparently due to the local water, too little fat in the diet, and excessive washing with too strong a soap It has been a great relief not to have to worry about dog bites, because of the great rarity of rabies in the United Kingdom

We have seen many cases of what is generally called either *gastro intestinal flu or epidemic nausea, vomiting, and* diarrhœa (in children), and these cases have a certain similarity to the disease called winter vomiting sickness Meningism, however, has not been prominent

One interesting disorder is what we have come to call the 'paraffin complex," which is due to misuse of paraffin heaters Many of our people use these heaters in poorly ventilated rooms and may forget to trim the wicks This produces headaches, injected conjunctivæ, and difficult breathing Several children were treated for "recurrent pink eye" before the nature of the process was recognised

Our problems with venereal diseases, adult tuberculosis, and catastrophic disease (diabetes, infarction, serious trauma) *reflects, I believe, the expected incidence* in an adult population of similar age composition in England

From this brief survey it can be seen that, though our problems are pretty much the same, certain aspects are relatively fresh to us In closing I should like to thank the local medical personnel for their unstinted help It will indeed be a pleasure to entertain any that may visit us in the U S A

Obituary

DOUGLAS ROBERT MacCALMAN

M D Glasg, F R C P E

Dr D R MacCalman had held chairs of psychiatry in Aberdeen and in Leeds His death at the age of 53 has come at a time when his knowledge and experience, especially in child guidance, will be greatly missed

He was the son of the late Rev D M MacCalman of Strachur Argyll, and he was educated at Glasgow Academy and at the University of Glasgow, where he was awarded the William Hunter medal in pathology After graduating M B in 1929 he held resident appointments at Glasgow Royal Infirmary and at mental institutions The following year he visited the United States and worked under Prof Macfie Campbell at the Boston Psychopathic Hospital and under Prof Adolph Meyer at the Johns Hopkins Hospital, Baltimore At Boston he took part in a large investigation into the cause of schizophrenia and he also studied variations in the blood-picture in different psychological states

On his return to this country in 1932 he became medical director of the Notre Dame child-guidance clinic in Glasgow The following year he took the M D with high commendation and in 1934 he joined the staff of the Royal Victoria Infirmary, Glasgow, as assistant physician for diseases of the nervous system He continued the work on the Rorschach test which he had begun in the United States

In 1935 he moved to London to take up the post of general secretary to the Child Guidance Council and psychiatrist to the Child Guidance Clinic

At that time the Council was financed and in every other way upheld by the Commonwealth Fund, and MacCalman's knowledge of the way things worked in America was of great value So also was his quiet determination to get child psychiatry on a sound footing in this country and he drew general physicians, and particularly pediatricians, as well as psychiatrists, academic psychologists, and the branches of the social services, into the work

In 1938 he was appointed the first (and only) Crombie Ross lecturer in psychopathology in the University of Aberdeen As a colleague later said "That region of hardy Calvinists and high thinking must have been a difficult field for a psychiatrist to cultivate But if his appointment was a bold experiment it was a successful one His assignment was to give instruction in the *causes and treatment of the* common neuroses, and to develop a child-guidance service and inpatient and out patient psychiatric services in the general teaching hospital At the height of the Normandy campaign in 1944 many psychiatric casualties found their way to the E M S hospital at Aberdeen, and MacCalman by early diagnosis and active treatment prevented the chronicity seen in the shell-shocked soldier By 1946, despite war-time handicaps, he had vindicated himself as a pioneer, and the University of Aberdeen promoted his department to professorial status and installed him as its first professor of mental health By the time he left in 1948 to take up his chair at Leeds the new department had been brought up to establishment, a comprehensive teaching programme organised, and the framework for an integrated mental health service constructed W M M, his successor, records

There is no feature of the present set up in Aberdeen that Douglas MacCalman did not either plan or foresee His effectiveness was all the more noteworthy because he was always so modest and unassuming His West Highland canniness and reserve concealed an astute and lively mind and his characteristic pawkiness many a time revealed itself in unexpected ways But his most outstanding quality during the years that I knew him was his fortitude

At Leeds he held at first the Nuffield chair of psychiatry, but in 1951, owing to ill health, he exchanged this for a part-time chair Much of the organisation of the psychiatric services in the Leeds hospital region shows evidence of his interests A flourishing child guidance department in the university psychiatric clinic gave him scope for his experience Last year he visited Australia as an adviser, and on his return to Leeds as part-time professor he supervised research projects which linked the university and the mental hospitals of the region He also fostered the Leeds Regional Psychiatric Association and he was active in the formation of the Mental Health Research Fund

E M C writes

MacCalman had a disarmingly quiet manner and a voice which was often difficult to hear Anyone supposing that he was unable to stand up to opposing opinion would deeply misunderstand the strength of his character Gentle he certainly was, but on occasion he could denounce sham and fumbling administration in terms of the keenest bitterness It was, however always done without rancour, and he always returned to the fight, tough and determined and deeply *intuitive as to the needs of the situation* whether in terms of a personal patient or of the laying on of a service

He died on Jan 31 He leaves a widow and a daughter

Appointments

Notes and News

COMMITTEE ON RADIOLOGY

A COMMITTEE to review the present practice in diagnostic radiology and in the use of radiotherapy in non malignant conditions has been set up by the Minister of Health and the Secretary of State for Scotland and has begun work. The decision to appoint this committee,[1] under the chairmanship of Lord Adrian, O M, accorded with a recommendation by the Medical Research Council's Committee on the Hazards to Man from Nuclear and Allied Radiation[2] The terms of reference of the new committee are

> To review the present practice in diagnostic radiology and the use of radiotherapy in non malignant conditions having regard to the Report of the Committee on the Hazards to Man of Nuclear and Allied Radiations and to make recommendations.

The members in addition to the chairman are

Prof J C McC Browne, F R C O G Sir Horace Evans F R C P Mr R J G Grewcock L D S Prof R J Kellar F R C O G Dr Peter Kerley Dr D R Maitland Prof W V Mayneord D SC Prof J S Mitchell F F R F R S Mr C Naunton Morgan F R C S Dr Kenneth Robson Mr T Holmes Sellors F R C S Mr G R. Seward M D S Prof F W Spiers D SC Prof E J Wayne F R C P Prof C A Wells F R C S Prof B W Windeyer, F F R

A JOURNAL OF MEDICAL HISTORY

IT is a pleasure to welcome at long last a major British journal dealing with *Medical History* Published by the antiquarian booksellers, William Dawson & Sons, and edited by Mr W J Bishop for many years librarian at the Wellcome Historical Medical Library, the first number of 90 pages is a handsome piece of work. Its decorative cover, incorporating a portrait of Thomas Linacre, worthily suggests the quality of the material it contains

This quarterly journal devoted to the history and bibliography of medicine and the related sciences is already the official organ of three history of medicine societies and of the Osler Club of London The five special articles in this number include an interesting account of Blue Books by Sir John Charles, and articles on the history of venous thrombosis on the plague in Cambridge, and on the health of James VI of Scotland and I of England There are also sections on texts and documents and on news notes, and queries, that may well be the strength of the journal Book reviews, society reports and a long list of medical anniversaries for 1957 are prominent features There are eight admirable full page plates The paper and type are excellent

There is at the moment a growing interest in medical history The new journal will be an added stimulant and it deserves full support both financial and literary from all who are interested in medical history or medical bibliography It is obtainable at £2 10s per annum from the publishers 4, Duke Street, Manchester Square, London, W 1

S H M O.s UNDERTAKING CONSULTANT DUTIES

COMMITTEE B of the Medical Whitley Council has agreed to consider claims for remuneration on the consultant scale submitted by senior hospital medical officers who are undertaking consultant duties[3] Application forms may be had from the secretary of the British Medical Association (B M.A House, Tavistock Square London W C 1) to whom the completed forms should be returned by March 2

HOSPITALS IN NORTHERN IRELAND

THE report for 1955[4] of the Northern Ireland Hospitals Authority shows that during the year admissions and out patient attendances were each about 1% more numerous than in the previous year The provision of new buildings at mental hospitals was helping to reduce over-crowding but, says the report, ' further building will be essential before the situation can be regarded as satisfactory ' Work continued on the planning of admission units for three mental hospitals

* * *

International Society of Internal Medicine

Sir Russell Brain F R C P has been elected president of this society The next meeting will be held in Philadelphia from April 24 to 26 1958

University of London

Dr M J Blunt, senior lecturer in anatomy at St Bartholomew's Hospital Medical College, has been appointed to the readership in anatomy at that college

Dr Blunt who qualified from Guy s Hospital in 1944 was resident surgical officer at Woolwich Memorial Hospital before he became lecturer in anatomy at the Royal Free Hospital Medical School He has also been visiting lecturer in anatomy at Queen Elizabeth College He took up his appointment at Barts last year His published work includes papers on the poster or wall of the inguinal canal and on the blood supply of the facial nerve.

Royal College of Physicians of Edinburgh

At a quarterly meeting of the college held on Feb 5, with Dr. A Rae Gilchrist, the vice president, in the chair, the following were elected to the membership

R F Gaymer M. A. O Halloran Misra Madhav Prasad James Allan, John Wilkinson Boris Levin Saifuddin Ahmed Elaine H McNeil Smith, Mohan Sankar Narayan Pathy Sharnagat Singh Khandpur Ram Dev Pasi B J Baldachin J R Roy A C Gibson Purnendu Samaddar Mukherji Flora M Bissett Smith J P F Fogarty N Z Sacks Tribhovanbhai Becharbhai Patel Anokchand Jain J H Learmonth Koratti Ardhanarishwara Krishnamurthy Bhim Prosad Mozoomdar W B Hudson Pitambar Dayal

Royal College of Physicians of Ireland

At a meeting of the college on Feb 1 the following were admitted to membership Elizabeth A. A. Awoliyi, W. D Linehan, R J P Skelly

British Medical Association

The annual meeting of the association will be held in Newcastle upon Tyne from Wednesday, July 10, to Friday July 19

Biochemical Society

A meeting of this society will be held at the Senate House of the University of London, W C 1, at 11 A M on Saturday Feb 23, when there will be a symposium on the structure and function of subcellular components

Central Council for Health Education

The council s summer school is to be held from Aug 20 to 30 at the University of North Wales, Bangor, on the promotion of health The speakers will include Dr J N Morris, Dr Wilfred Barlow, and Dr C O Carter Further particulars can be had from the medical director of the council, Tavistock House, Tavistock Square, London W C 1

Lady Tata Memorial Trust

The trustees of this fund invite applications for grants, scholarships, or fellowships for research on blood diseases, with special reference to leukæmia, in the academic year beginning next October Programmes of research on any aspect of malignant disease which may throw light on problems of leukæmia will be considered, and awards may be made to investigators of any nationality, working in any country where payment can be made Particulars and application forms may be had from the secretary of the (European) Scientific Advisory Committee of the trust, Chester Beatty Research Institute, Fulham Road, London, S W 3 Applications must be submitted before March 31

Society for General Microbiology

The general meeting of this society will be held at the Royal Institution, Albemarle Street, London, W 1, from April 15 to 17 At 6 P M on Monday, the 15th, Dr Andre Lwoff of the Pasteur Institute Paris, will give the Marjory Stephenson lecture on the Notion of Virus This lecture will be open to non members On Tuesday and Wednesday, the 16th and 17th, there will be a symposium on microbial ecology and the speakers will include Dr Jane Gibson, Dr E S Anderson, Dr C H Andrewes F R S, and Dr G S Wilson Further particulars may be had from the office of the society c/o Institute of Biology, 41, Queen s Gate, S W 7

International Symposium on Curare and Curarising Substances

This symposium will be held in Brazil from Aug 5 to 17 During the first week meetings will be held at the University of Brasil in Rio de Janeiro and during the second week visits will be made to Manaus (Instituto Nacional de Pesquisas de Amazonia) and to Belem (Instituto Agronomico do Norte) Further particulars may be had from Prof C Chagas, Instituto de Biofisica, Universidade do Brasil, 458, Avenida Pasteur Rio de Janeiro, Prof Daniel Bovet, Instituto Superiore di Sanita 299, Viale Regina Elena, Rome, or Prof P B Carneiro, Delegation du Brésil, UNESCO, 19, Avenue Kleber, Paris 16e

International Symposium of Clinical Psychopharmacology

Further particulars of this symposium, which is to be held at Milan from May 9 to 11, may be had from Dr S Garattini, Via A del Sarto, 21, Milan

European Organisation for Research on Fluorine and Dental Caries Research

A meeting of this organisation will be held at Malmö, Sweden, from June 15 to 17 Further particulars may be had from Professor Syrrist, Royal Dental School, Malmo

Education for Motherhood

A seminar for medical officers of health on health education for the expectant mother is to be held at St John House, Collingham Gardens, London, S W 5, from Feb 26 to March 1 Further particulars may be had from the medical director, Central Council for Health Education, Tavistock House, Tavistock Square, W C 1

Atoms and Health

The Royal Society of Health, with the United Kingdom Atomic Energy Authority, is holding an exhibition on this subject at 90, Buckingham Palace Road, London, S W 1, from Monday, March 18 to Friday, May 31 It will be open to the public on Mondays to Fridays from 10 A M to 5 P M

Hearing-tests for Cerebral Palsied Children

A film on this subject has been made at the Centre for Spastic Children, Chelsea in coöperation with the audiology unit of the Royal National Throat, Nose, and Ear Hospital The film is silent (16 mm, 650 ft), and a script to go with it can be obtained or a lecturer supplied from the centre, 61, Cheyne Walk, London, S W 3

American Broadcasts on British Medicine

During February and March, in its weekly broadcasts on Thursday evenings *For Doctors Only*, the New York Academy of Medicine is including a series of lectures on British medicine The lecturers are to be Sir David Campbell, Lord Cohen of Birkenhead, Sir Charles Dodds, Dr J R Duthie, Prof C F W Illingworth, Prof John McMichael, Prof Alan Moncrieff, Sir James Paterson Ross, Mr T Holmes Sellors, Prof B W Windeyer, and Prof L J Witts

Ministry of Health Appointments

Mr Dennis Vosper, the Minister of Health, has appointed Mr John Barter, M P for Ealing North, as his parliamentary private secretary He has appointed Mr P Benner to be his private secretary and Mr E F Cooper to be his assistant private secretary

Mr J K Vaughan-Morgan, the parliamentary secretary to the Ministry, has appointed Mr J P Cashman to be his private secretary

National Association for Maternal and Child Welfare

The annual conference of this association will be held at Church House, Westminster, London, S W 1, from June 26 to 28 The theme of the conference is to be safeguarding the health of mother and child, and the speakers will include Dr Charlotte Naish, Dr J W B *Douglas*, Dr W C Cockburn, Dr Ian Taylor, Sir Weldon Dalrymple Champneys, and Prof F R G Heaf Further information may be had from the secretary of the association, Tavistock House North, Tavistock Square, W C 1

International Poliomyelitis Conference

This conference will be held at Geneva from July 8 to 12 The subjects chosen for discussion include vaccination against poliomyelitis, enteric viruses producing disease simulating poliomyelitis, studies on cultured mammalian cells, general considerations of viruses, respiratory distress in patients with poliomyelitis, and care of patients severely stricken by poliomyelitis Further information may be had from the secretariat of the conference, *Hôtel du Rhône, Geneva*, Switzerland

French Government Exchange Scholarships

Under a reciprocal arrangement with the Centre National de la *Recherche Scientifique*, the Medical Research Council invite applications from British workers in medical science for two scholarships tenable at research institutions in France during 1957–58

The scholarships will carry a maintenance allowance of 50 000–70 000 francs a month *married men will receive a supplementary* allowance and provision will be made for travelling expenses Further particulars may be had from the secretary of the council, 38 Old Queen Street London S W 1 with whom applications must be lodged by March 31

M.D Lpool, F.F.A R C S
READER IN ANÆSTHESIA, UNIVERSITY OF LIVERPOOL

The story of modern anæsthesia can, I think, be summarised in one word—control During the past ten to fifteen years, new drugs have been introduced which, little by little, have enabled us accurately and surely to regulate the bodily mechanism of our patients, until today it is almost possible to manipulate basic physiology as one might play an organ—pulling out this stop or suppressing that in order to achieve an effective blend of safety for the patient and excellent conditions for the surgeon

After the first great discovery of general anæsthesia in 1846, which gave man some merciful control over the consciousness of his suffering fellows, the next most significant step was taken when Griffith and Johnson (1942), by the use of curare, demonstrated the clinical feasibility of the control of muscle tone It was very soon realised that there was no longer any excuse for the turbulent belly and the struggling surgeon, and by 1946 there should have been, in Frankis Evans's picturesque phrase, " no question of a vast abdomen moving in gusty waves " (Evans 1946)

But this was not just a new tool in the anæsthetist's bag, it had a greater significance than the mere smoothing out of a troublesome anæsthesia Time has shown that the effects of this discovery extend over a very wide field indeed One has only to think of the need which at once arose for better-trained anæsthetists who could be safely entrusted with this potent new therapeutic weapon, and as a result of this improved educational background the raising of the status of the anæsthetist, not only economically but (more important) in the esteem of his colleagues Still more important, however, were two new " controls " which were at once placed in our hands

It is true that before curare control of the respiration had been practicable by a combination of central nervous depression and excessive ventilation of the lungs But the procedure was not satisfactory, and, because of the widespread depression of bodily function produced by deep anæsthesia, it demanded a price With curare, respiratory control by peripheral paralysis of the muscles of respiration was possible, and even inevitable if curare was to be used safely and effectively Artificial ventilation of the lungs was imperative whenever curare was given, and thus anæsthetists became experts in controlled ventilation The floodgates to a great stream of research into the various types of artificial respiration were opened, and led to a renewed interest among clinicians in the physiological principles of pulmonary ventilation As a result too, anæsthetists have been able to make considerable contributions towards the treatment of diseases involving the respiratory apparatus, such as poliomyelitis, tetanus and various forms of poisoning

Perhaps, however it might be held that an even more significant result followed the introduction of curare In 1946 I wrote, " the age of deep anæsthesia with its attendant respiratory and circulatory depression and postoperative dangers should have passed away " The use of curare was in effect the first step in achieving control of the circulation—for all the anæsthetic agents of sufficient potency when given in the dosage required to achieve muscular relaxation, seriously disturb the regulation of circulatory stability All through the central nervous and cardiovascular systems these agents exert their effects—function is depressed From the vital medullary centres regulating vasomotor control and the heart-rate, through the servo-mechanisms in the aorta, carotid body, and great veins, down to the very pump itself, the myocardium—all are depressed by anæsthetic agents The kaleidoscopic fluctuations of the vast capillary bed are slowed and their responsiveness to hæmorrhage is lost Zweifach and his colleagues had shown in 1945 that deep anæsthesia abolished the response to transfusion after hæmorrhage As with hæmorrhagic collapse so also with autonomic reflexes—if afferent stimuli from the mesentery, mediastinum, or liver-bed produced reflex circulatory collapse—evidenced by low blood-pressure and bradycardia—the collapse, under deep anæsthesia, tended to persist On the other hand, the very light anæsthesia that was possible when curare was used left the protective reflexes unimpaired and the reflex control of vasomotion still sensitive and adequate for compensatory responses

It was appreciated that surgical trauma in so light a plane of anæsthesia might have its own hazards Crile (1921) had warned that the brain which was only half asleep might respond to trauma by initiating circulatory collapse But the experience of the past ten years has shown that light anæsthesia does not in fact conduce to circulatory collapse Thoracotomies are now often carried out under nitrous oxide/oxygen anæsthesia alone, and anæsthesia per se has never produced less deterioration of the circulation than at present

This very absence of " shock " in patients only just asleep turned our minds and thoughts to the study of the fundamentals of circulation and respiration, and even of mind and consciousness itself So light is our anæsthesia, with patients often moving frowning, or showing other reactions to stimuli, despite complete unawareness, that we have begun to wonder what indeed is meant by unconsciousness Is it perhaps, after all, only loss of memory from instant to instant ?

One recalls the words of John Snow (1847) as he contemplated the effect of the invention of anæsthesia

> " The power we have acquired, through the discoveries of our medical brothers in America of inducing at will and with perfect safety such a state of insensibility as we should probably have thought to be alarming cannot be without its influences on the progress of our knowledge of the diseases of which insensibility form a symptom. and of the function of the nervous system generally "

Induced Hypotension

The next advance in our control of the circulation stemmed directly from these developments As the circulatory dynamics were little affected by light anæsthesia, a new problem arose—bleeding Of course, at first, curare the new drug itself, was thought to be causative This was inevitable for any new drug is likely to be blamed for every unexpected reaction of the patient to whom it is given

Undoubtedly, failure to appreciate the need for adequate pulmonary ventilation played a part, but the light plane of anæsthesia now being used was the principal cause My colleague, Dr McLoughlin (1954), has shown that in these light stages of anæsthesia (1) the amount of bleeding is inversely proportional to the plane of anæsthesia, and (2) cyclopropane causes one and a half times as much bleeding as ether In Edinburgh around 1948 cyclopropane was extensively used, and Gillies (1952) himself has acknowledged that this undoubtedly contributed to their ready appreciation of the dry surgical field provided by total spinal block Evolution is, in a sense, inevitable, and it is idle to speculate on alternatives, but I hazard a guess that, had not curare

---

* The Alex Simpson Smith memorial lecture of the West London Hospital Medical School delivered on Oct 30, 1956.

been introduced to anæsthesia, we should not now use induced hypotension

However that may be, to return to my previous simile of the organ, Gillies in 1948 pulled out a full diapason stop by demonstrating to anæsthetists, and (perhaps unfortunately) to surgeons, the practicability and apparent safety of deliberate lowering of the blood-pressure (Griffiths and Gillies 1948) The field of operation now approached the ischæmic pallor of the post mortem room, and when the original method of complete sympathetic block by high spinal anæsthesia was supplanted by the use of ganglioplegic drugs it was inevitable that this particular control would be used widely In hæmorrhagic operations the need for transfusion was reduced It seemed clear that one pint of blood retained in the circulation was worth two citrated and out of a bottle Neurosurgical, plastic, and otolaryngological operations, hitherto hampered by congestion, were facilitated, and enthusiasm has waxed strong Quite apart from the obvious advantage of a bloodless field of operation, it has been suggested (and this is always propounded by the advocates of every new anæsthetic technique) that hypotension induced by drugs protected against those circulatory responses which are so often misleadingly described under the general term "shock" (Wyman 1953) It is thought that this might be due to the blocking of afferent autonomic impulses or to the avoidance of the stress of over compensatory vasoconstriction and the free flow of blood through the capillaries

Dangers of Hypotension

With a new advance in clinical practice, a compromise has often had to be made between, on the one hand, submitting our patients to remedies incompletely investigated and, on the other hand, overlong delay in exploiting their salutary and beneficial effects In any case, in medicine, as in every other sphere, knowledge is doomed always to be incomplete and there cannot but be some empiricism in therapeutics

This empiricism was certainly exercised in the clinical application of hypotension, but I believe time has shown that widespread use of this technique is not justified More investigations than one (Armstrong Davison 1951, Van Bergen et al 1954) have yielded electrocardiographic evidence suggesting myocardial ischæmia during hypotensive anæsthesia, and Nilsson in Sweden (1953) obtained, by flicker fusion tests, evidence of subclinical cerebral damage during these operations There are certainly ample experimental data now to confirm the obviously expected interference with cerebral circulation (Saunders 1954, Hughes 1955) and a change in cortical function has been shown by alteration in the electro encephalogram (Van Bergen et al 1954) There is some danger of renal ischæmia where drugs are used to produce hypotension (Aas and Bergen 1949) or when the hypotension is prolonged (Armstrong Davison 1951) These and other similar investigations lead one to think that the a-priori reasoning on which the safety of the technique was first deduced was perhaps too naïve The argument was propounded in these terms

> The head of pressure driving blood through the capillary bed under normal conditions is of the order of 30 mm Hg The bulk of the peripheral resistance maintaining normal blood-pressure is in the arterioles, and, therefore, when all arteriolar tone is abolished (as in a condition of complete vasodilatation) and the patient is at rest under anæsthesia, the blood-pressure could be lowered considerably, without losing the requisite head of pressure to ensure capillary perfusion

The validity of this argument depends on the relation of the blood volume to the capacity of the vascular bed There is evidence that sometimes there may be disproportion during anæsthesia with low blood pressure, and then hypoxia is bound to follow (Van Bergen et al 1954) Furthermore, though it may be convenient in theory to look upon the human circulatory system in mechanical terms as a pump flushing a liquid through a series of pipes of variable diameter and resistance, there are factors, in particular disease, which make the analogy inapplicable

Therefore, though induced hypotension was at first enthusiastically welcomed by many surgeons and anæsthetists, it is not surprising to find that recent surveys have shown that this advance has exacted a price—some might say a heavy price Four years ago an editorial in one of the principal anæsthetic journals stated that there have been "unexpected deaths in apparently healthy people undergoing operations of no particular severity" (*Anæsthesia* 1952) Factual evidence for these "unexpected" deaths is now available The Association of Anæsthetists established, in 1949, a committee to investigate deaths during anæsthesia Of the first 1000 fatalities freely reported to that committee, 17 were in patients who had had hypotension While the committee cautiously reported that "it is not suggested that in any instance the use of intended hypotension was necessarily deleterious" (*Anæsthesia* 1953) from the data it would appear that in at least 5 patients the hypotension was probably gravely implicated, and in the remainder (which included cases of death due to reactionary hæmorrhage, cerebral and coronary vascular accidents, and anuric renal failure) the low blood pressure state probably contributed to death Four years ago Hampton and Little (1953) published the result of a questionnaire sent to 602 specialist anæsthetists in this country From the data collected, covering 21 000 patients submitted to hypotension, it appeared that this technique was implicated in a mortality-rate of 1 in 500 and a morbidity-rate of 1 in 38 In the United States a similar inquiry covered 6805 hypotensive anæsthetics and showed a mortality of 1 in 136 Even allowing for mismanagement and the wrong application of the technique, this is a morbidity-rate far greater than might be expected from normotensive anæsthesia, and an indictment that cannot be ignored

It is still widely claimed that in young and healthy people this technique is perfectly safe when used by experienced anæsthetists But youth and health do not necessarily go together, and disease is not always clearly apparent In this context a cardiologist has stated "that severe coronary heart-disease may be symptomless and produce no changes in the electrocardiogram and there is no reliable way of detecting it until myocardial ischæmia is produced" (Hayward 1952) He points out that "the state of the peripheral arteries gives no indication as to the health of the coronary vessels, and an increasing number of cases of coronary thrombosis is occurring in young, apparently healthy men, who at autopsy are found to have advanced coronary disease" He concludes by suggesting that in "certain types of operations where success may depend on the bloodless operative field the potential risk of the methonium compounds causing cardiac or cerebral ischæmia may have to be accepted"

These risks should no longer be taken In the first place, hypotension should be reserved for those cases in which it is clearly imperative because of the nature of the surgery this would limit it to neurosurgical, and perhaps some otolaryngological and plastic operations, and thoracotomies in the presence of aortic coarctation In the second place, even in these cases, I believe that the risks can be greatly reduced by combining hypotension with moderate hypothermia—that new "control" which has been given to us, control of the metabolism Sir James Learmonth who was in at the very birth of techniques for inducing low blood pressure, must have had this in his mind when he suggested that "a combination of the hypotensive and cooling techniques has many possibilities in facilitating and extending surgical procedures" (Learmonth 1953) It seems to me that the law of supply and demand applies just as much in the economy of the body human as in that of the body politic, and, if it is necessary to restrict the supply of blood to the tissues then, if damage is to be avoided with certainty, it is imperative to reduce the demand for blood At 30°C the body's oxygen consumption is about 50% of normal, and even at 32°C it is still reduced by 35%, our experience with hypothermia convinces me that to reduce the body-temperature to this level is safe and well within the competence of those who should practise induced hypotension It seems doubtful whether, except for the briefest periods, hypotension should ever be used without this additional safeguard It is time-consuming perhaps—but it seems that a couple of hours of preparation, which in practice can become of a very routine nature, is a small price to pay for the additional safety in those cases (and this I emphasise because I believe they are really not numerous) where hypotension is essential

Hypothermia

An enormous bibliography has accumulated on the subject of hypothermia and within the past eighteen months the Royal Society of Medicine has held no less than four meetings to discuss the subject I do not wish to cover the same ground again, for the usual effects of cooling should by now be well known I do, however, wish to give some evidence for the safety of cooling by the surface application of ice when it is combined with the administration of light anæsthesia and drugs such as chlorpromazine to ensure vasodilatation and freedom from shivering

Since 1953 I, and the anæsthetists associated with my department and the neurosurgical unit, have used hypothermia in over 250 patients The great majority, 180, have been patients undergoing neurosurgery in fact the neurosurgical unit is at present using this technique in 10–12 patients a month 46 have had general surgical operations, and the remainder have had vascular or cardiac operations In only one have we used the extra corporeal method

Methods of Cooling

It has been suggested that the method used to achieve hypothermia is "relatively unimportant" (Lucas 1956) I regard that as an oversimplification It seems likely that each method has its own indications and certainly each has its advantages and disadvantages The argument for some form of extracorporeal cooling in patients having cardiac or vascular surgery in the thorax is strong until the chest is opened and the diagnosis confirmed the patient need not be exposed to whatever risks are entailed in the cooling process It is perhaps less time consuming though both in animal experiment and in our patient we were surprised at the time required to cool and rewarm The vein-to-vein method (Ross 1954), modified by Sir Russell Brock (1956) in which blood is circulated from one vena cava through the cooling unit to the other vena cava, prohibits a very rapid lowering of temperature In these circumstances the heart is cooled more rapidly than the remainder of the body It is a fact that, with this method overenthusiastic cooling produces quite evident cardiac deterioration even while the general body temperature is high

After all by the surface method one can achieve enough cooling within two hours It seems to me that in the type of case for which hypothermia is used, the time factor should be relatively unimportant

It may be suggested that the extracorporeal method is more controllable Thus it is often alleged that the continued fall of temperature after removal of the ice makes surface cooling particularly unpredictable But this is much less of a problem if adequate vasodilatation is maintained by chlorpromazine or similar drugs, for in this way the gradient of temperature from the body core to the surface is considerably reduced Changes in posture during the cooling in order to prevent pooling of the blood probably also help, but the danger of this "after drop," as it has been called, is much lessened by its anticipation All our experience has endorsed the finding (Burrows et al 1956) that the degree of "after-drop" is related to the patient's build Lean patients with little adipose insulation cool rapidly and have little or no "after-drop," while the well-covered and insulated body cools slowly and the fall of temperature continues for some time after removal of the ice In the well-covered, perhaps the tyro would be well advised to stop active cooling, as Virtue (1955) suggests, at two-thirds of the required fall in temperature Shivering is no longer seen premedication with chlorpromazine and light anæsthesia have prevented this undesirable feature of surface cooling

Arrhythmias

A testimony to the safety of the method is the fact that except after intracardiac manipulation, we have had no case of ventricular fibrillation This seems to me not only evidence of controllability but also of interest because the 180 neurosurgical patients have not, in fact, had artificial ventilation (except when there has been acute respiratory depression, as when surgical manœuvres have interfered with the floor of the 4th ventricle) Vanderwater et al (1955) have produced results which suggest that, even though respiration is depressed and slowed in these circumstances, there is not necessarily a decrease in the pH of the blood, in fact there may occasionally be a tendency to alkalinity In contrast to the neurosurgical patients, all the others have been very actively ventilated It is, however, easy to demonstrate in dogs that ventricular fibrillation can be caused, below the critical temperature of 28°C, by sudden ventilation in cases where the respiration has been depressed I suspect that it is important to maintain steady ventilation and avoid sudden changes

Another sinister arrhythmia is bradycardia Intense bradycardia during hypothermia has been described in dogs by Cookson and Di Palma (1955) who believed it was due to direct depression of the sino auricular node That it was not due to vagal overactivity is suggested by the failure of vagotomy or atropine to reverse the condition We have seen this three times, and I am grateful to Dr Dundee for these cases 2 failed to

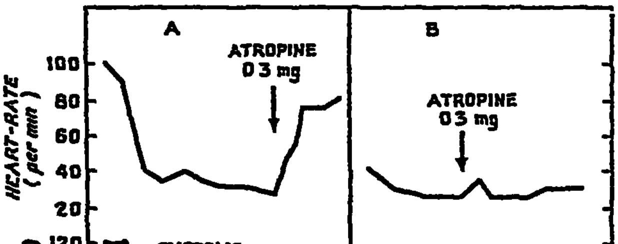

Fig 1—2 patients with bradycardia during hypothermic anæsthesia (A) Man aged 46 with a frontal lobe tumour bradycardia reversed by atropine (B) Woman aged 28 with an arteriovenous anomaly no change after atropine

respond to atropine, but in the other it was successful in removing the arrhythmia (fig 1)

Blood-coagulation

One of the complications of hypothermia which has exercised us has been its effects on blood-coagulation A patient whom we cooled by the surface method succumbed to intractable oozing which continued after the operation This was for portacaval anastomosis, and the hypothermia was used in an attempt to obtain a relatively dry field of operation In fact, the advanced liver cirrhosis, with a significantly reduced prothrombin index, contra indicated hypothermia He received 21 pints of blood, and he died forty-eight hours later, apparently from a transfusion reaction (Dundee et al 1953)

There are many references in the literature to uncontrollable postoperative hæmorrhage in animals (Helmsworth et al 1955) and to submucosal hæmorrhages in the viscera following hypothermia (Parkins et al 1954, Deterling et al 1955) The influence of a fall in temperature on the coagulation time of blood in vitro is well known (fig 2), but there is more to it than this Ross (1956) has drawn attention to the dangers of prolonged hypothermia and has shown that in dogs, at any rate, the proportion of recoveries from the hypothermic state falls very significantly after three to five hours He emphasises the particular danger of uncontrollable oozing

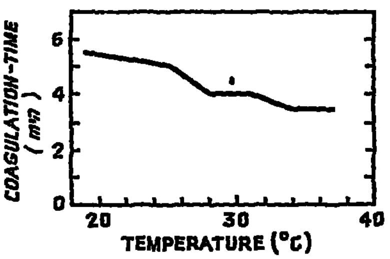

Fig 2—Effect of temperature on coagulation-time of blood as estimated by hair capillary method

During experiments to determine the steroid output at low temperatures, we have maintained 16 dogs, cooled by the surface method, at temperatures below 30°C for seventy-two hours 3 did not survive this period Of the remaining 13, we have attempted resuscitation in 9 without success, although they have survived for two or three days after rewarming Of these 9, 3 almost, but not quite, recovered consciousness At necropsy, apart from a boggy œdema of the tissues and transudation of fluid into the peritoneum and pleural cavities, hæmorrhage and congestion are the predominating features There is intense congestion in the liver accompanied by central lobular necrosis (fig 3), and in the kidneys (fig 4) accompanied by fluid exudation into the glomerular tufts The distal tubules show separation of the cells from the basement membrane, which is prominent and convoluted The suprarenals (fig 5) are characterised by vacuolation and loss of cells in the medulla, and necro in the cortex (fig 6). These changes are similar to (but more severe than) those described by Knocker (1955) in dogs cooled for up to three hours It cannot be stated that they are not due to hypoxia, for blood oxygen was not estimated, but in these experiments any sign of hypoxia would have been treated by assisted respiration

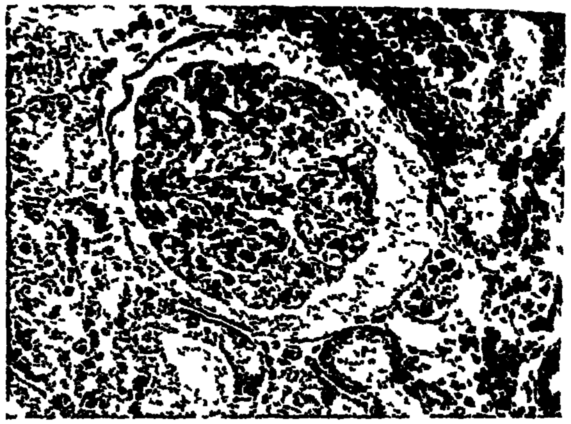

Fig 4—Kidney of dog (×360) maintained at 29°C for 72 hours. Congestion and exudate into glomerular capsule Prominence of basement membrane

Certainly the predominant characteristic—i e, reduction in the coagulation ability of the blood—could not be so explained The lungs are so congested that they can only be described as full of blood, and the bladder shows extensive submucosal hæmorrhages Oozing from each needle prick after withdrawal of blood samples and troublesome hæmorrhages from the wound edges were further evidence of the loss of clotting-power

Examination of the coagulation characteristics of the blood gave some explanation of these findings (fig 7) There was a slowing of the thrombin fibrinogen reaction and a fall in the platelet counts as the days passed, with corresponding changes in the coagulation time and prothrombin index

Though care was taken to maintain the electrolyte and fluid balance of these animals, they were not given protein, there may have been a loss of fibrinogen, associated with a general fall in plasma proteins But similar experiments in control dogs which were kept anæsthetised with pentobarbitone (though at normal temperature) for the same period showed that this was not the explanation These control dogs recovered rapidly and perfectly normally, and their blood coagulation characteristics were little altered (fig 8)

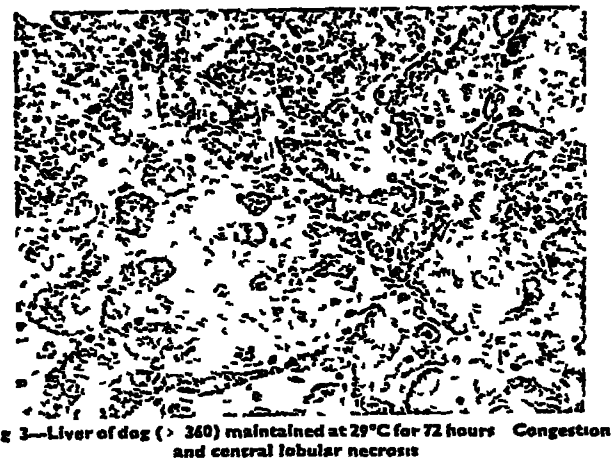

Fig 3—Liver of dog (× 360) maintained at 29°C for 72 hours Congestion and central lobular necrosis

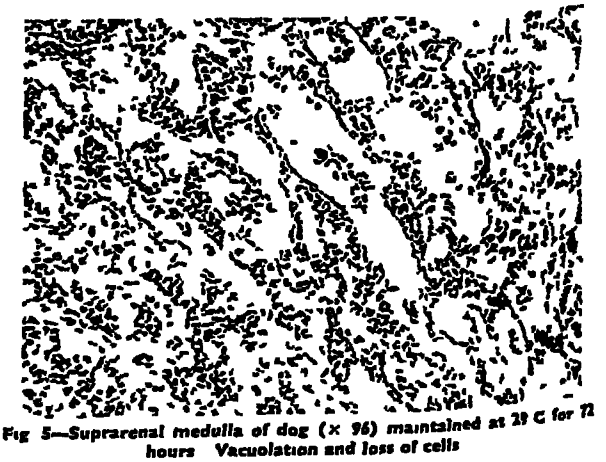

Fig 5—Suprarenal medulla of dog (× 96) maintained at 29 C for 72 hours Vacuolation and loss of cells

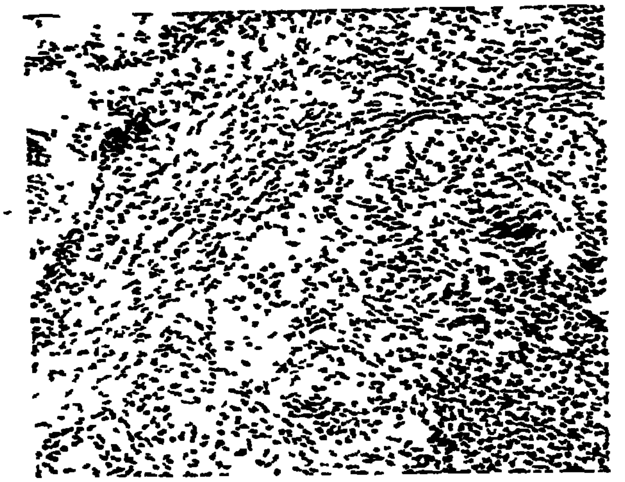

Fig 6—Suprarenal cortex of dog (× 96) maintained at 29°C for 72 hours Cell necrosis. Disappearance of typical cells.

The slowed fibrinogen-thrombin reaction in the cooled dogs might be due to loss of fibrinogen from depression of liver function, but Owren (1947) has shown that the optimum concentration of fibrinogen for blood-coagulation is 20% of that normally found. Fulton (1946) gives an even lower level. The possibility arises of the presence of a heparin-like substance Suomalainen (1954) in Finland has shown that during hibernation, hedgehogs have a greater prolongation of coagulation-time than can be accounted for by the fall in temperature This is associated with a proliferation of the mast cells which are deposited in the submucosa of the intestine and in the region of the bronchioles These cells are believed to liberate heparin. We have not yet estimated the heparin level of the blood of our animals but if it were increased this would account for all our findings A high heparin level might be due to liberation of an excess or to a delay in excretion of heparin at these low temperatures

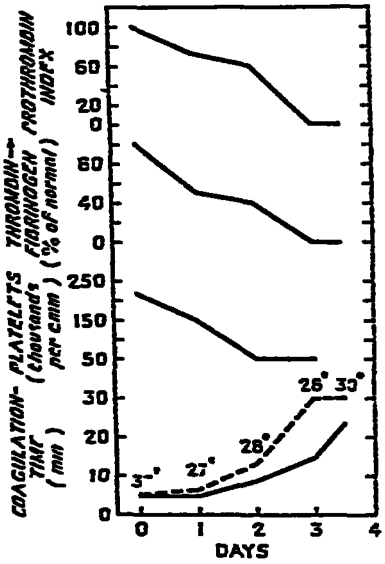

Fig 7—Coagulation characteristics of dog maintained at 29°C for 72 hours. The coagulation-time (hair-capillary method) is shown at the dog's temperature at the time of estimation and at normal body-temperature 37°C.

Practical Considerations

These observations may have little significance in regard to short periods of hypothermia—e.g., during operation—except to warrant care in patients in whom the blood-coagulation is not normal, but I think they may be of some importance where prolonged hypothermia is attempted in treating brain-stem injury or other conditions Very low temperatures should probably be avoided, and a check kept on the coagulation characteristics of the blood

With the exception of the single patient with reduced liver function that I have mentioned we have not seen this type of trouble with the 250 surface-cooled patients: and some have been kept at 30°C for up to four days

However all that may be, few will deny that these difficulties with blood-clotting are much less likely to be experienced with surface cooling than with the extracorporeal methods It is well known that the circulation of blood through tubes and valves leads to hæmolysis and loss of platelets and so interferes with coagulation This can be a real danger. Of 40 patients at the Mayo clinic maintained on a heart-lung apparatus during operations on the open heart (Kirklin et al 1956), 1 is reported to have died from intractable postoperative hæmorrhage It is suggested that this was due to the large amount of hæmolysis present (plasma-hæmoglobin 1.5 g per 100 ml.) The clotting elements of the blood were not investigated

There is reason to suspect that other workers have had more difficulty We have lost a patient from incoagulability of the blood after operation who was cooled by the simple apparatus described by Lucas (1956) modified by the use of siliconised rubber tubing instead of the less elastic vinyl plastic She was a girl aged 22 with pulmonary stenosis, treated by open valvotomy

Helmsworth and Cole (1956) have sought to show that changes of this nature in the blood are greater with surface cooling than with the extracorporeal method (see table) But their results might be misleading, because the estimation was made with the surface method at 23°C, and with the extracorporeal method at 28°C Apart from the possible effects of the difference in temperatures it seems certain that further circulation of the blood through the apparatus in order to achieve the extra 5°C of cooling would have altered the result very considerably and made it more justly comparable to that obtained with the surface method.

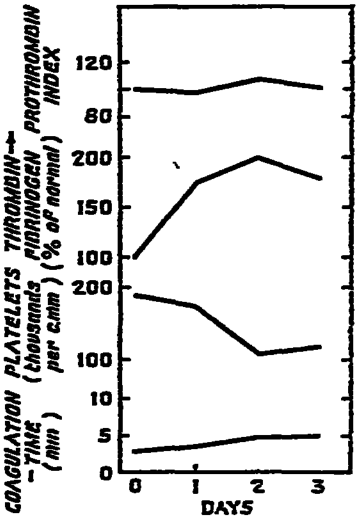

Fig 8—Coagulation characteristics of dog maintained anæsthetised with pentobarbitone for 72 hours at normal temperature.

CHANGES IN 11 ANIMALS COOLED BY IMMERSION (ABOVE) AND EXTRACORPOREAL CIRCULATION (BELOW) (ADAPTED FROM HELMSWORTH AND COLE 1956)

Immersion	Average at normal temperature	Average change at 23°C
Hæmatocrit (%)	46.4	[illegible]% increase
Platelet-count (per c.mm.)	324,700	50.7%
Leucocyte-count (per c.mm.)	12,6[illegible]	52.[illegible]%
Total eosinophil-count (per c.mm.)	3[illegible]	3[illegible]% decrease
Mean [illegible]	33.9	61%

Extracorporeal circulation	Average at normal temperature	Average change at 28°C
Hæmatocrit (%)	[illegible]	[illegible]% increase
Platelet-count (per c.mm.)	34[illegible]	34.[illegible]%
Leucocyte-count (per c.mm.)	12,[illegible]	51.2%
Total eosinophil-count (per c.mm.)	[illegible]	33.1% decrease
Mean [illegible]	32.2	4[illegible]%

What of the future of hypothermia ? It is foolish to prophesy, but I think that there is no doubt that it has established itself as irreplaceable as an adjuvant to hypotension in general surgery and especially in neuro surgery, and I reiterate that I believe that hypothermia should always be used, except perhaps for the briefest period of hypotension in young people In therapeutics it is likely to remain effective in treating cases of hypermetabolism Thyrotoxic crises are a rarity in these days, but we have found hypothermia extremely useful in the 2 cases we have met Similarly it has a place in the treatment of hyperpyrexial states, and in cases of brain or brain-stem injury associated with œdema

Heart-lung Pumps

In open cardiac surgery, there is a distinct decline in enthusiasm for hypothermia and an increasing tendency to favour some form of pump oxygenator to assume the function of the heart and lungs This has been particularly evident in the United States since the work three years ago by Miller et al (1953) and the great advances made by Lillehei and his associates (1955)

I am not at all sure, however, that hypothermia will be replaced by these methods The differential brain-cooling suggested and successfully used by the Japanese workers Kimoto et al (1956) would seem in theory to remove many objections to cooling Furthermore, the recent experiments on the supra-cooling of mammals raises the question of whether this approach has been fully exploited The introduction of extracorporeal circulation through a pump and mechanical oxygenator has all the hazards in regard to hæmolysis and altered coagulation to which I have referred

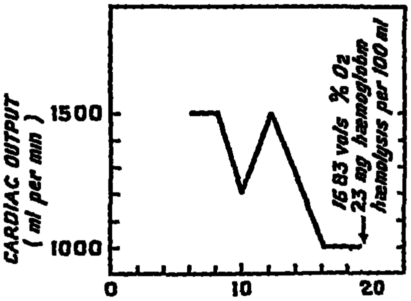

Fig 9—Dog s heart lung preparation perfused with human blood working against a peripheral resistance of 120–130 mm Hg Oxygen and free hæmoglobin estimated at 20 minutes

It seems that we are faced with a dilemma We require a pump with an output of the order of more than 2 litres a minute Such large-output pumps, however, entail circulation of the blood through the pump more frequently than do pumps of small output, and the cellular components of the blood are subjected to more trauma Perhaps the answer will he with moderate cooling and a pump giving the smaller order of output

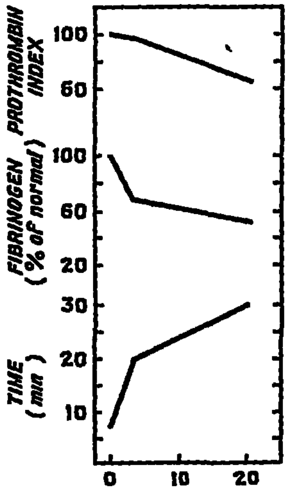

Fig 10—Dog's heart-lung preparation perfused with human blood Blood-coagulation studies

I should like to conclude by describing an attempt we have made to reduce these hazards For some years I have been carrying out various pharmacological investigations with the Starling heart lung preparation, and Mr Leslie Temple suggested that, in view of the success achieved with the heterologous lung oxygenator, the heterologous heart should be used as a pump Helped by generous donors of human blood, we have worked together on this project and, as with all such enterprises, have waxed alternately manic and depressive in our enthusiasm I think, however, we have established that the heart and lungs of the dog can be used to pump and oxygenate human blood We have not been able to demonstrate any incompatibility of the sample of human blood which has circulated in the preparation with a sample of the same blood which has not circulated This might, I think, be expected after the report, by Campbell et al (1956), on the successful use of the dog's lungs to oxygenate blood in cardiac surgery in 7 patients We have, however, been faced with several problems, such as the tendency of the lungs to become œdematous Acting on the experience of Campbell and his colleagues, we thought this could be overcome by adequate washing out with dextran, but our longest period with a good output and reasonable oxygenation has been forty-five minutes, and occasionally lung œdema comes on considerably earlier (fig 9) The heart and lungs are not so easy to wash out as the lungs alone, but our present technique of cooling the preparation before introducing the dextran and human blood is enabling us to get wash outs with only 7000 cells per c mm

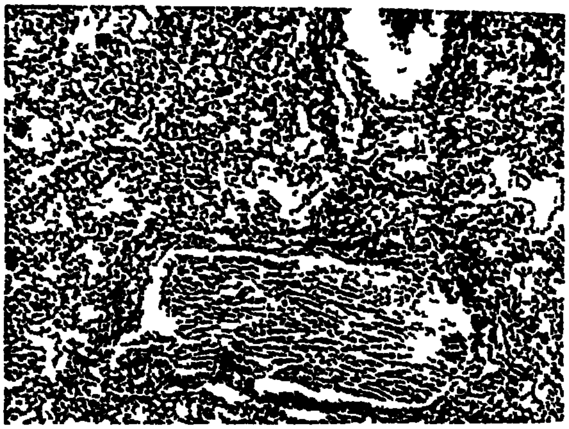

Fig 11—Dog's lung (× 95) after perfusion with human blood Congestion, œdema, and deposition of fibrinogen in pulmonary vessel

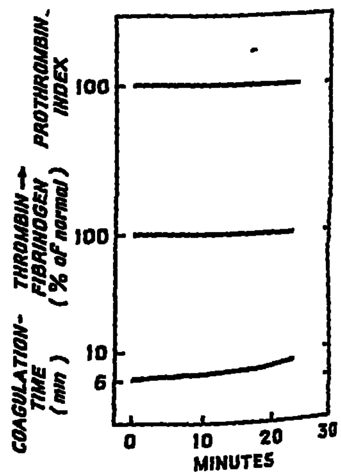

Fig 12—Dog's heart lung preparation perfused with human blood Blood coagulation studies after insertion of nylon filter in circuit

It was disappointing, at first, to find that hæmolysis and altered coagulation of the blood are experienced with this biological pump, just as with mechanised heart lungs The amount of hæmolysis has varied, and, though we have had some preparations with less than 2 mg of plasma hæmoglobin per 100 ml, usually there is about 136 mg We hope to reduce this considerably by using an all-plastic apparatus which is being prepared

The early preparations progressively lost fibrinogen, and the blood coagulation studies showed disturbing features (fig 10) The fibrinogen was being deposited in the lungs (fig 11), but the serious feature was the considerably altered prothrombin index But at the sug gestion of Dr Harry Wilson, of the department of pharmacology, we are now filtering the blood through nylon and seem to have overcome this difficulty (fig 12), though we have not established that the difference is in fact due to the nylon filter

It is too early to say whether this type of preparation has any future in clinical application It does hold out the possibility of a cheap and efficient heart lung pump, and one which in theory should be less destructive to corpuscles and carry its own servo regulatory mechanisms

Conclusion

My theme may be summed up in the word " control " I have above all endeavoured to control myself and to avoid that type of dogmatism which would have me labelled, as was the character in *Measure for Measure*, " a proud man, drest in a little brief authority "

I have suggested that induced hypotension, both on a priori grounds and in the light of recent surveys, demands a high price, and that surface cooling down to 30°C is, in experienced hands, practical and safe It should be regarded as an adjuvant to hypotension in most, if not all, cases I have expressed a foreboding that extracorporeal cooling will be found to incur its own hazards, which are likely also to attend the use of any mechanised heart-lung pump I have suggested a new approach to the heart-lung pump problem which remains to be explored

Dr Robert Coope, in his little book *The Quiet Art*, quotes a Negro's prayer, and it would be difficult to find a better morning supplication for all who are involved in this work and who, by constant endeavour and thought, are striving to improve the lot of our patients by more effective and safer control of the circulation

> " Lord, help me to understand that you ain t goin' to let nothin come my way that you and me together can't handle "

I would like to express my gratitude to my colleagues in the department for their very considerable assistance in the experiments from which I have quoted, and to Mrs Todd, the biochemical technician in my department, for the various blood investigations I am greatly indebted also to Mr H P Harding, of the department of veterinary pathology, for the examination of many pathological specimens and slides and to Mr W A Lee of the central department of photography, for the preparation of the photomicrographs Without the full coöperation of Dr D Lehane, of the Liverpool Regional Blood Transfusion Centre, it would not have been possible to have carried out the experiments with the heart-lung preparation, and I am extremely grateful to the generous donors who gave, and are continuing to give their blood for this work

THE CHANGING PATTERN OF LEUKÆMIA

A J LEA
M.B Birm
SENIOR MEDICAL OFFICER, MINISTRY OF PENSIONS AND NATIONAL INSURANCE

JOHN D ABBATT
M.B Edin , D M R
MEMBER OF THE EXTERNAL SCIENTIFIC STAFF, MEDICAL RESEARCH COUNCIL, DEPARTMENT OF MEDICINE, POSTGRADUATE MEDICAL SCHOOL OF LONDON

THERE are striking differences in the published estimates of the relative incidence of acute and chronic leukæmia, extreme values for the acute form being 26% (Morganti and Cresseri 1952) and 61% (Gunz and Hough 1956) Undoubtedly part of this is due to the use of different criteria to decide which cases are to be included under the heading of acute leukæmia Another cause is the great difference in age at onset of the two forms of leukæmia, which makes it difficult, and sometimes impossible, to compare two series of cases Yet another difficulty is that there is evidence that the incidence of leukæmia varies with social status and geographical location (Hewitt 1955) There are other reasons for these differences which are not so obvious as those cited above For instance, there has been a change in the relative age-incidence of acute and chronic leukæmia since 1940, at least in the age group 15–55

Material and Methods

Our material consists of all cases of leukæmia which occurred in the Armed Forces between Sept 4, 1939, and Dec 31, 1955, and for which application for pension was made to the Ministry of Pensions and National Insurance We have thus obtained details of 655 cases, but there may be others Previous experience has shown that some cases are always missed from such a series, owing to errors in coding, &c , but no grounds have been found for suggesting that selective factors are involved in such omissions

For the present purposes the following data were recorded in each case sex, date and place of birth date of onset of leukæmia, date of death or duration of disease until Dec 31, 1955 Such a series is not entirely free from selection as regards the following factors

(1) *Sex* —Only 10 of the 655 were females , owing to their small number they were included with the males

(2) *Age* —This is necessarily limited to the ages of serving personnel In the present case the ages ranged from 18 to 63 years

TABLE I—RELATIVE INCIDENCE OF ACUTE AND CHRONIC LEUKÆMIA, ACUTE LEUKÆMIA BEING DEFINED AS A DURATION OF NOT MORE THAN *Six* MONTHS

Age at onset (yr)	Years of onset 1940–44			1945–49			1950–54		
	Acute	Chronic	Total	Acute	Chronic	Total	Acute	Chronic	Total
15–24	69 (*72·6%*)	26	95	37 (*71·2%*)	15	52	17 (*60·7%*)	11	28
25–34	68 (*64·2%*)	38	106	59 (*58·4%*)	42	101	16 (*55·2%*)	13	29
35 or more	35 (*41·2%*)	50	85	47 (*51·1%*)	45	92	22 (*61·1%*)	14	36
All ages	172 (*60·1%*)	114	286	143 (*58·4%*)	102	245	55 (*59·1%*)	38	93

Figures in parentheses are percentages of the acute type for each age group for each onset period

(3) *General Health*—The cases were drawn from a population who were, at the date of enlistment, considered to be of the standard of physical and mental fitness necessary for service in the Armed Forces. Since the comparisons to be made are entirely within the series, this fact is of no importance in the present investigation.

In every case we saw the hospital records including the hæmatological findings, and satisfied ourselves about the diagnosis of leukæmia. We consider that our series consisted entirely of cases of leukæmia, so far as could be ascertained by the diagnostic methods in use at the time of the investigation. On the other hand, we found wide differences of opinion on the histological type of leukæmia. We also noted cases diagnosed as aplastic anæmia where we have reason to regard the diagnosis with suspicion.

TABLE II—MEAN AGES AT ONSET OF ACUTE AND CHRONIC LEUKÆMIA, ACUTE LEUKÆMIA BEING DEFINED AS A DURATION OF NOT MORE THAN *Six* MONTHS

—	Years of onset 1940–44	1945–49	1950–54
Mean age, acute (yr)	28·7	31·7	33·1
Mean age, chronic (yr)	33·9	34·6	32·8

In view of the uncertainty expressed by most workers on the "typing" of cells in acute leukæmia we adopted an arbitrary definition; *a case of acute leukæmia was* one in which the disease did not last more than six months from onset to death. A further difficulty then arose—the determination of the date of onset. We have taken this as being the first date on which the patient complained of any symptom which is included in the standard descriptions of leukæmia (Whitby and Britton 1953, Wintrobe 1956).

Results

The cases were divided into three groups according to the year of onset, 1940–44, 1945–49, and 1950–54. This excluded cases arising before 1940 and since 1954 from this part of the investigation, leaving 624, which were again divided into age groups at date of onset 15–24, 25–34, and 35 years or more. The data are shown in table I.

It will be seen that the incidence of acute leukæmia, all ages, was remarkably constant in each of the five-year periods of onset, being 60·1%, 58·4%, and 59·1%. Comparison of the mean age at onset of the two types, however, showed an increase in the acute type and a decrease in the chronic (table II).

The increase in mean age at onset in the acute cases was found to be significant; the decrease in the mean age at onset in the chronic cases was found to be no greater than that expected from chance variations (see appendix).

The change in the age at onset of the acute type was mainly due to an increase in the proportion of acute cases in the older age groups, but there was also a decrease in the proportion in the younger ages (fig 1).

Such a change could be explained if the average age of Forces personnel had increased during the period under investigation. The age distribution of men in the Forces for 1941–54 inclusive was obtained from the Central Statistical Office, and the means calculated. For the three five-year periods 1940–44, 1945–49, and 1950–54 these were found to be 28·7, 27·0, and 23·9 years respectively. These mean ages, with the mean ages at onset of the two types of leukæmia, are shown in fig 2.

It will be seen that, far from explaining the observed changes, consideration of the mean age of the Forces personnel emphasises the extent of the changes which have taken place.

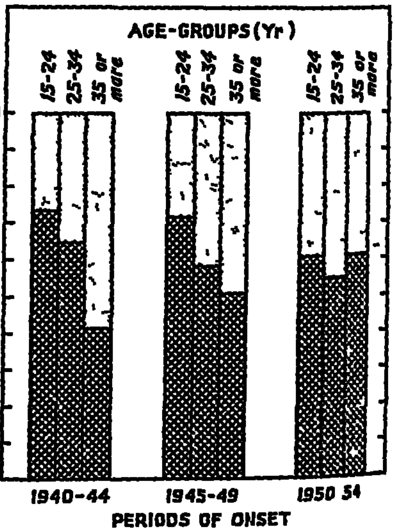

Fig 1—Change in incidence of acute and chronic leukæmia since 1940: stippled, chronic; hatched, acute.

It was appreciated that these results might have depended on our arbitrary six-months' definition of acute leukæmia, and that a different definition might not show any such change. Hæmatological opinion is divided on the classification of leukæmia by its duration. Some hæmatologists recognise a subacute type which lasts from six to twelve months, whereas others include cases lasting twelve months or less with acute leukæmia (Committee for Clarification of Nomenclature of Cells and Diseases of Blood and Blood-Forming Organs 1950). We therefore re-examined the data, defining acute leukæmia as that form of the disease which did not last more than twelve months. The results are given in tables III and IV.

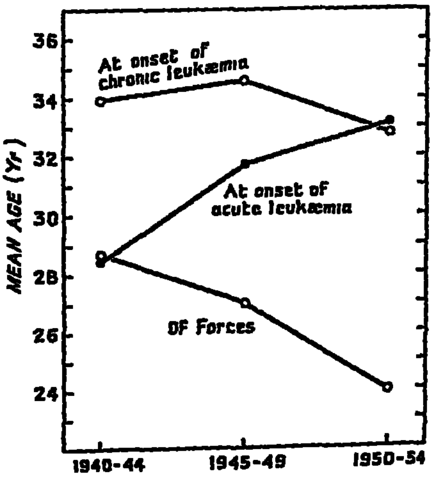

Fig 2—Mean ages of Armed Forces and at onset of acute and chronic leukæmia

It will be seen that the change in pattern with time is still present. It was found that the increase in the mean age at onset of the acute type had the same degree

TABLE III—RELATIVE INCIDENCE OF ACUTE AND CHRONIC LEUKÆMIA, ACUTE LEUKÆMIA BEING DEFINED AS A DURATION OF NOT MORE THAN *Twelve* MONTHS

Age at onset (yr)	Years of onset								
	1940–44			1945–49			1950–54		
	Acute	Chronic	Total	Acute	Chronic	Total	Acute	Chronic	Total
15–24	77 (*81 1%*)	18	95	45 (*86 5%*)	7	52	20 (*71 4%*)	8	28
25–34	79 (*74 5%*)	27	106	75 (*74 3%*)	26	101	20 (*69 0%*)	9	29
35 or more	45 (*52 9%*)	40	85	59 (*64 1%*)	33	92	27 (*75 0%*)	9	36
All ages	201 (*70 3%*)	85	286	179 (*73 1%*)	66	245	67 (*72 0%*)	26	93

Figures in parentheses are percentages of the acute type for each age-group for each onset period

of significance as with the previous definition, and that the decrease in the mean age at onset of the chronic type was again not significant (see appendix)

Discussion

Additional evidence which may be of importance for the explanation of this change in the pattern of leukæmia is contained in the tables of age-specific death-rates of leukæmia for England and Wales prepared by Dr R A M Case and Miss J T Pearson (unpublished) Calculations based on these tables show that the ages at which no real change in the mortality from leukæmia has taken place are from 20 to 34, and that these are approximately the same in both sexes (These changes, for males, are shown in fig 3)

It now becomes possible to bring together certain more or less isolated facts about leukæmia and to draw conclusions from them The facts are as follows

(1) The mortality from leukæmia in the general population is known to be increasing sharply, both in this country and in others

(2) There are two peaks in the mortality from leukæmia, in infancy and from middle age onwards, and this is true for both sexes

(3) In the age group 20–34 there has been virtually no change in the mortality from leukæmia

(4) Ionising radiation is known to be leukæmogenic both in animals and in man (Warren 1956, Medical Research Council 1956)

(5) Radiation is the only known leukæmogen to which every living thing on the planet is to some degree exposed (Spiers 1956)

(6) There has been an increase in the man made contribution to background radiation, both from the appurtenances of civilisation and as a result of nuclear explosions (Medical Research Council 1956)

(7) There has been a significant increase in the mean age at onset of acute leukæmia since 1940

From these facts we have drawn the following conclusions

(1) It is improbable that the increase in the incidence of leukæmia can be solely due to heavy doses of irradiation such as from radiotherapy or from close association with nuclear explosions The Medical Research Council (1956), investigating leukæmia and ankylosing spondylitis, found only 37 cases of leukæmia in a heavily irradiated population of 13 352 patients over a period of twenty years and it is obvious that there cannot be many such populations in existence

(2) Though we are not here dealing with the leukæmia of infancy, it seems probable that at least in some cases it is associated with irradiation in utero (Stewart et al 1956) Such irradiation is delivered to embryonic tissues and compared with background levels constitutes a high radiation dose

(3) We are left with an excess of cases of leukæmia occurring after the age of 35 in people who have not been subjected to heavy doses of radiation In the absence of evidence for genetic determination of these cases it is reasonable to assume that they arise as a result of some agent acting after conception. Such an agent may well be exposure to long term low dose radiation If we accept this hypothesis, it is necessary to postulate either a certain minimal cumulative dose or a time lag after the exposure to the responsible agent, and/or leukæmia to be the result of a somatic mutation. The results of experiments on animals suggest that a somatic mutation is the most probable explanation (Loutit 1957), and that in man there is a latent period before leukæmia is detectable by present techniques A latent period has been found in leukæmia occurring in cases of irradiated ankylosing spondylitis and in those following the Japanese atomic bombing Japanese cases were still occurring, apparently with undiminished frequency, ten years after the bombing (Medical Research Council 1956)

It is clearly to be understood that we are not advancing the hypothesis that all leukæmia is due to radiation, and we are well aware that the picture has been oversimplified Other possible leukæmogens have been suggested—e g, sulphonamides The use of these drugs greatly increased during the period of our investigation, but there does not, at present, appear to be any firm evidence that they are leukæmogenic We hope to be able to produce evidence on this point and later on other suggested leukæmogens At present we can only point out that a possible explanation of at least some of the

TABLE IV—MEAN AGES AT ONSET OF ACUTE AND CHRONIC LEUKÆMIA, ACUTE LEUKÆMIA BEING DEFINED AS A DURATION OF NOT MORE THAN *Twelve* MONTHS

—	Years of onset		
	1940–44	1945–49	1950–54
Mean age at onset acute (yr)	29 0	31 7	33 2
Mean age at onset, chronic (yr)	35 0	36 2	32 3

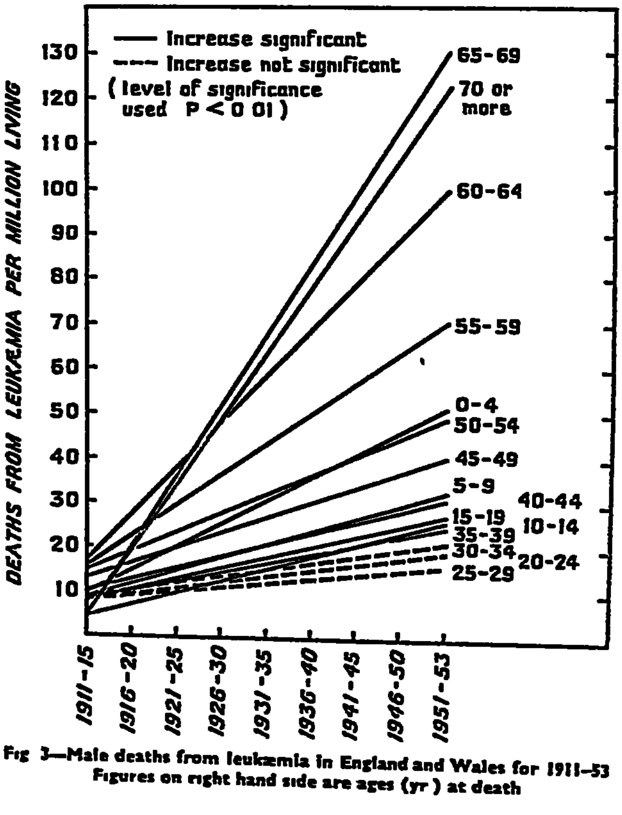

Fig 3—Male deaths from leukæmia in England and Wales for 1911–53 Figures on right hand side are ages (yr) at death

increase in the mortality from leukæmia, and of the advance in the age at onset of the acute type which we have shown to be taking place, is the increasing amount of man made radiation to which we are all subjected In particular we emphasise the increase in diagnostic radiology in the Western countries between 1900 and the present date (the period covered by the tables from which fig 3 had been prepared) We tried to estimate the amount of diagnostic radiation received by the patients in our present series, but the position was so complicated by the possibility of unrecorded routine mass radiography that the assessment of this particular factor proved to be impossible We appreciate that such a hypothesis is not a "good" one, in the sense that it cannot be subjected to experimental verification If, however, this hypothesis is correct, a continued increase in the incidence of leukæmia is to be expected unless exposure to man-made radiation is adequately controlled

Summary

624 cases of leukæmia arising in members of the Armed Forces in 1940–54 were examined

A significant increase in the mean age at onset of the acute type was found both with a duration of less than six months and with a duration of less than twelve months No significant change was found in the mean age at onset of chronic leukæmia during the same period

There was a decrease in the mean age of Forces personnel during the same period, which accentuates the change found in acute leukæmia

It is probable that environmental factors are responsible both for this change and for the known increase in the general mortality from leukæmia One such factor may be man-made additions to the background radiation

We wish to acknowledge our indebtedness to the Medical Research Council's working party on leukæmia research, under whose auspices this investigation is being made We are most grateful for helpful advice and criticism from Dr J V Dacie, Prof A Bradford Hill, Prof J S Mitchell, Dr E E Pochin, Dr F G Spear, and Prof L J Witts We have to thank Dr R A M Case and Miss Joan T Pearson for permission to use their unpublished work, the Central Statistical Office for details of and permission to publish the mean ages of Forces personnel, and the Ministry of Pensions and National Insurance for providing access to the relevant war pension records and for permission to publish the data extracted from them

Appendix

Age specific Death-rates for Leukæmia (table v) —Tables of death rates for leukæmia for England and Wales for 1911–53 in five year periods and for each 5 year age-group from 0–4 to 70 or more male and female, have been prepared by Dr R A M Case and Miss J T Pearson as part of the programme of the Chester Beatty Research Institute From these tables we have calculated the "best straight line" for each 5 year age group, and each of these lines has been compared, by the χ^2 method, with a line drawn parallel to the X axis through the point Y = mean death-rate for the age group (The best straight line is here defined as that line for which the sum of the squares of the residuals is a minimum) These lines are shown for males in fig 3 The features to which we especially wish to draw attention are the non significant increases for the age groups 20–24, 25–29, and 30–34, and the rapidly growing significant increases for the older age groups

TABLE V—SIGNIFICANCE OF DIFFERENCES IN MEAN AGES AT ONSET

Type	Difference of mean ages at onset (yr)	Standard error of difference (yr)	Significance
"Acute" = not lasting more than 6 mos			
Acute	4 4	1 7	P less than 0 01
Chronic	1 1	2 0	not significant
"Acute" = not lasting more than 12 mos			
Acute	4 2	1 5	P less than 0 01,
Chronic	2 7	2 3	not significant

BLOOD PYRUVIC-ACID AND ALPHA-KETOGLUTARIC-ACID LEVELS IN LIVER DISEASE AND HEPATIC COMA

THE liver is intimately concerned with intermediate carbohydrate metabolism, and the raised blood keto acid levels reported in severe liver disease (Amatuzio and Nesbitt 1950) might indicate failure of this process The application of paper chromatographic (Cavallini et al 1949) and enzyme methods (Segal et al 1956) have now allowed separate analysis of α-ketoglutaric and pyruvic acids Both these acids are transported from the periphery to the metabolic pool in the liver Raised levels of α-ketoglutaric acid in the blood have been reported in liver disease (Seligson et al 1952) and increases in both acids noted when there is complicating hepatic coma (Amatuzio and Nesbitt 1950, Carfagno et al 1953, Walshe 1955) In this paper the blood levels of pyruvic acid and α-ketoglutaric acid are reported in a series of patients with liver disease, with and without neuropsychiatric changes An attempt has been made to determine the mechanism of the changes in keto acid levels and to assess the usefulness of these estimations as a routine clinical procedure in the management of patients with liver disease

The blood ammonium level is often raised in hepatic coma (McDermott and Adams 1954, Traeger et al 1954, Phear et al 1955), and Bessman and Bessman (1955) have observed removal of ammonium by the brain and peripheral tissues as reflected by an arteriovenous difference This peripheral and cerebral removal of ammonium is probably due to combination of α keto glutaric acid and ammonia to form glutamic acid, which in turn is aminated by another molecule of ammonia to form glutamine Bessman and Bessman (1955) have suggested that in hepatic coma the unmetabolised ammonium combines with the α ketoglutaric acid of muscle and brain until the supply of this acid is exhausted Such a deficiency will eventually interfere with the efficient working of the Krebs tricarboxylic acid cycle in which α-ketoglutaric acid is an essential link The blood

TABLE I—NORMAL VENOUS KETO ACID LEVELS

Reference	Method	No of observations	Mean α ketoglutaric acid ± S.D. (µg per 100 ml)	Mean pyruvic acid ± S.D. (µg per 100 ml)
Seligson et al 1952	Chromatography of 2,4 dinitrophenylhydrazine derivatives after ethyl acetate extraction	18	200 ± 23	656 ± 151
Walshe 1955	Chromatography of 2,4 dinitrophenylhydrazine derivatives after ethyl acetate extraction	16	143 (range 86–302)	230 (range 160–280),
Smith and Taylor 1955	Chromatography of 1,2 diamino 4 nitrobenzene derivative	7	100 ± 20	310 ± 70
Segal et al 1956	Enzyme	26		660 (range 390–860)
Present series	Chromatography of 2,4-dinitrophenylhydrazine derivatives after ether extraction	19	57 ± 12	541 ± 111

keto acid levels were therefore compared with those of blood-ammonium The level of blood ammonium was also raised by giving oral ammonium chloride, and the effect on blood keto acid levels observed

Thioctic (lipoic) acid is a co enzyme essential for the formation of active acetate and so obligatory for the efficient working of the tricarboxylic acid cycle and hence for the metabolism of pyruvic acid (Ochoa 1954) In view of the increased pyruvic acid values noted in hepatic coma, thioctic acid has been recommended for its treatment (Rauch 1954, Steigmann and Canthuati 1956) Results in 4 patients are now reported

Case-material and Methods

38 patients with liver disease were studied, of whom 16 showed neurological changes 33 patients suffered from portal cirrhosis 1 from biliary cirrhosis and 2 from acute virus hepatitis A patient with typical neurological changes had a normal liver histologically and macroscopically, and a large extrahepatic portal systemic collateral circulation Another had deep jaundice associated with Hodgkin's disease of the liver and was in coma All patients received parenteral vitamin B supplements The control group (16) were members of the hospital staff or volunteer patients without liver disease or other conditions such as congestive heart failure or thyrotoxicosis, which are known to affect the blood keto acid level

The neurological condition was graded 0 (normal), 1 (minor disorders of consciousness and the motor system) 2 (gross disorders of consciousness and the motor system), or 3 (coma) The portal collateral circulations were assessed by transplenic portal venography (Atkinson et al 1955)

On 70 occasions blood from resting patients after an all night fast was drawn simultaneously from artery and antecubital vein On 20 occasions only venous blood was obtained Ammonium was estimated by a slight

Age specific Death rates for Leukæmia (table v) —Tables of death rates for leukæmia for England and Wales for 1911–53 in five year periods and for each 5 year age group from 0–4 to 70 or more male and female, have been prepared by Dr R A M Case and Miss J T Pearson as part of the programme of the Chester Beatty Research Institute From these tables we have calculated the "best straight line" for each 5 year age group, and each of these lines has been compared, by the t^2 method, with a line drawn parallel to the X axis through the point Y = mean death-rate for the age group (The best straight line is here defined as that line for which the sum of the squares of the residuals is a minimum) These lines are shown for males in fig 3 The features to which we especially wish to draw attention are the non significant increases for the age groups 20–24, 25–29, and 30–34, and the rapidly growing significant increases for the older age groups

TABLE V—SIGNIFICANCE OF DIFFERENCES IN MEAN AGES AT ONSET

Type	Difference of mean ages at onset (yr)	Standard error of difference (yr)	Significance
"Acute" = not lasting more than 6 mos			
Acute	4 4	1 7	P less than 0 01,

The liver is intimately concerned with intermediate carbohydrate metabolism, and the raised blood keto acid levels reported in severe liver disease (Amatuzio and Nesbitt 1950) might indicate failure of this process The application of paper chromatographic (Cavallini et al 1949) and enzyme methods (Segal et al 1956) have now allowed separate analysis of α-ketoglutaric and pyruvic acids Both these acids are transported from the periphery to the metabolic pool in the liver Raised levels of α ketoglutaric acid in the blood have been reported in liver disease (Seligson et al 1952) and increases in both acids noted when there is complicating hepatic coma (Amatuzio and Nesbitt 1950, Carfagno et al 1953, Walshe 1955) In this paper the blood levels of pyruvic acid and α-ketoglutaric acid are reported in a series of patients with liver disease, with and without neuropsychiatric changes An attempt has been made to determine the mechanism of the changes in keto acid levels and to assess the usefulness of these estimations as a routine clinical procedure in the management of patients with liver disease

The blood ammonium level is often raised in hepatic coma (McDermott and Adams 1954, Traeger et al 1954, Phear et al 1955), and Bessman and Bessman (1955) have observed removal of ammonium by the brain and peripheral tissues as reflected by an arteriovenous difference This peripheral and cerebral removal of ammonium is probably due to combination of α keto glutaric acid and ammonia to form glutamic acid, which in turn is aminated by another molecule of ammonia to form glutamine Bessman and Bessman (1955) have suggested that in hepatic coma the unmetabolised ammonium combines with the α ketoglutaric acid of muscle and brain until the supply of this acid is exhausted Such a deficiency will eventually interfere with the efficient working of the Krebs tricarboxylic acid cycle in which α-ketoglutaric acid is an essential link The blood

TABLE I—NORMAL VENOUS KETO-ACID LEVELS

Reference	Method	No. of observations	Mean α-ketoglutaric acid ± S.D. (μg. per 100 ml.)	Mean pyruvic acid ± S.D. (μg. per 100 ml.)
Seligson et al. 1952	Chromatography of 2: 4-dinitrophenylhydrazine derivatives after ethyl acetate extraction	18	200 ± 23	686 ± 161
Walshe 1955	Chromatography of 2: 4-dinitrophenylhydrazine derivatives after ethyl acetate extraction	16	143 (range 86–302)	230 (range 160–280)
Smith and Taylor 1955	Chromatography of 1: 2-diamino-4-nitrobenzene derivative	7	100 ± 20	330 ± 70
Segal et al. 1956	Enzymic	20		600 (range 380–860)
Present series	Chromatography of 2: 4-dinitrophenylhydrazine derivatives after ether extraction	19	57 ± 12	541 ± 141

keto-acid levels were therefore compared with those of blood ammonium. The level of blood ammonium was also raised by giving oral ammonium chloride, and the effect on blood keto-acid levels observed.

Thioctic (lipoic) acid is a co-enzyme essential for the formation of active acetate, and so obligatory for the efficient working of the tricarboxylic-acid cycle and hence for the metabolism of pyruvic acid (Ochoa 1954). In view of the increased pyruvic-acid values noted in hepatic coma, thioctic acid has been recommended for its treatment (Rauch 1954, Steigmann and Canahuati 1956). Results in 4 patients are now reported.

Case-material and Methods

38 patients with liver disease were studied, of whom 16 showed neurological changes. 33 patients suffered from portal cirrhosis, 1 from biliary cirrhosis, and 2 from acute virus hepatitis. A patient with typical neurological changes had a normal liver histologically and macroscopically, and a large extrahepatic portal-systemic collateral circulation. Another had deep jaundice associated with Hodgkin's disease of the liver and was in coma. All patients received parenteral vitamin-B supplements. The control group (16) were members of the hospital staff or volunteer patients without liver disease or other conditions, such as congestive heart failure or thyrotoxicosis, which are known to affect the blood keto-acid level.

The neurological condition was graded 0 (normal), 1 (minor disorders of consciousness and the motor system), 2 (gross disorders of consciousness and the motor system), or 3 (coma). The portal collateral circulations were assessed by transplenic portal venography (Atkinson et al. 1955).

On 70 occasions blood from resting patients after an all-night fast was drawn simultaneously from artery and antecubital vein. On 20 occasions only venous blood was obtained. Ammonium was estimated by a slight

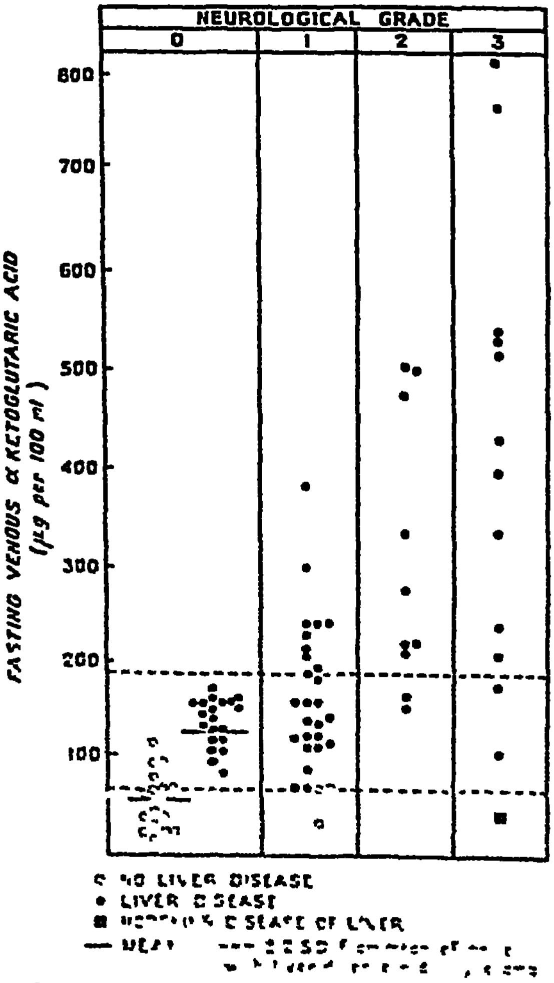

Fig. 1—Fasting venous α-ketoglutaric acid levels related to grade of coma.

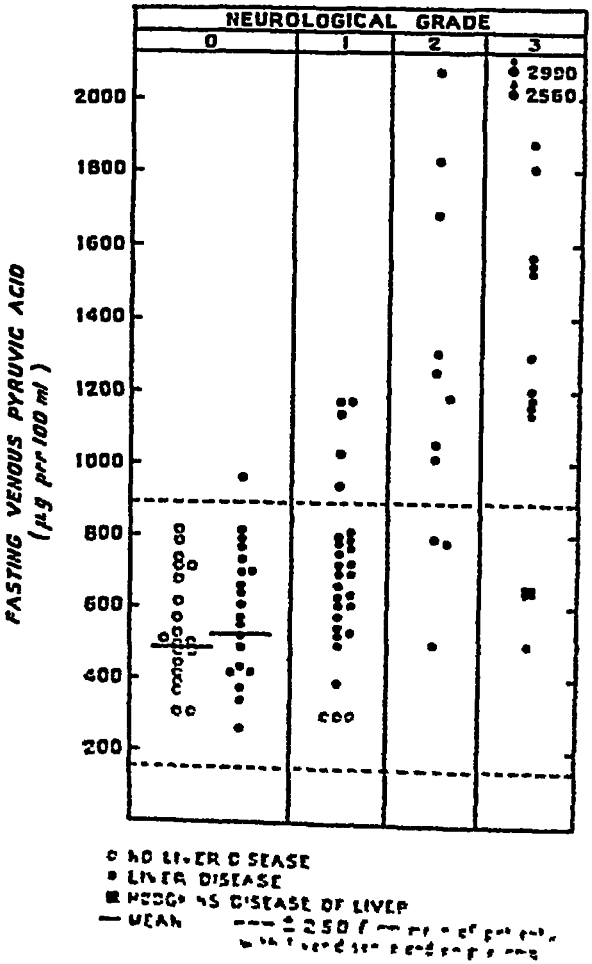

Fig. 2—Fasting venous pyruvic acid levels related to grade of coma.

modification of Conway's (1950) microdiffusion method (Phear et al 1955) Normal arterial values for this method are less than 1 μg per ml Pyruvic acid and α-ketoglutaric acid were estimated by a modification of the method of Cavallini et al (1949), the 2 4-dinitrophenylhydrazine derivatives were extracted with ether and separated by chromatography (de Groote et al 1955)

10 fasting subjects with cirrhosis of the liver were given 3 g ammonium chloride orally, arterial and venous α-ketoglutaric-acid, pyruvic-acid, and ammonium levels were estimated at once and thirty, sixty, ninety, and a hundred and twenty minutes later

Thioctic acid was given intravenously in doses ranging from 66 to 88 mg over periods of forty two to sixty hours Fasting blood and keto acid levels were obtained at the beginning and end of treatment

Results

Normal Blood Keto acid Levels

Like previous workers we found a wide scatter of values, especially for pyruvic acid (table I) The present values for blood α-ketoglutaric acid were lower than those previously published

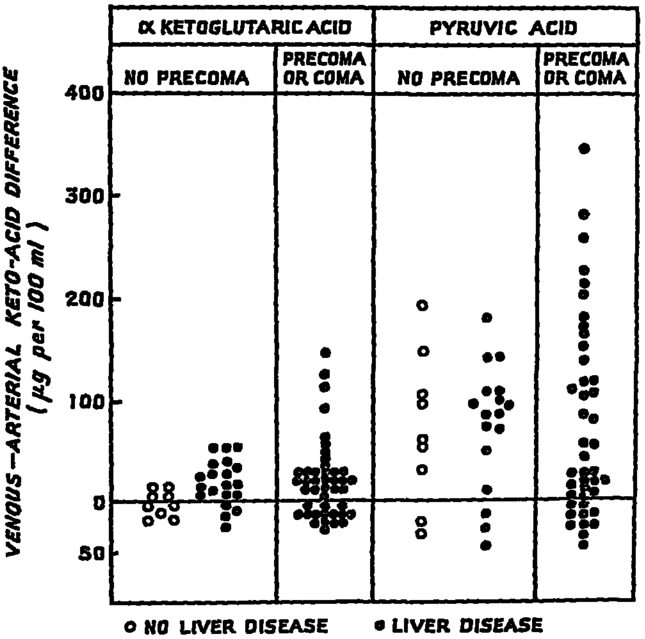

Fig 3—Fasting venous-arterial difference of keto-acids in relation to neurological state Values above the line indicate the peripheral tissues giving up keto acids

Venous α-ketoglutaric acid and Pyruvic-acid Levels and the Neurological Condition

Results of 73 estimations in 38 patients were correlated with the neurological condition at the time of sampling (figs 1 and 2) In patients with neuropsychiatric complications, a "raised" value of either keto-acid differed more than 2 standard deviations from the mean value obtained for patients with liver disease but without hepatic pre coma

Mean fasting venous α-ketoglutaric acid levels (fig 1) in patients with liver disease and no signs of impending coma was 131 μg per 100 ml ± 30, this is significantly higher than the control group (p = 0 01) Levels were raised in 8 of 30 patients in grade-I precoma, 8 of 10 in grade II coma, and 10 of 12 patients in grade III coma

A patient whose liver was invaded by Hodgkin's tissue had a normal level All the patients with grade I neurological changes and values less than 100 μg per 100 ml had relatively good liver function and a large portal systemic shunt, and were suffering from the syndrome of chronic portal-systemic encephalopathy (Summerskill et al 1956) The three lowest values were obtained from the woman with this syndrome who had a normal liver

TABLE II—VARIATIONS IN VENOUS KETO ACID LEVEL OF 4 FASTING PATIENTS WITH CIRRHOSIS OF THE LIVER

Patient	9 A M	10 A M	11 A M	Maximum variation from initial value (%)
	α Ketoglutaric acid (μg per 100 ml)			
1	251	240	240	− 4
2	64	64	73	+ 14
3	111	105	132	+ 19
4	174	169	183	+ 5
	Pyruvic acid (μg per 100 ml)			
1	775	710	740	− 6
2	483	468	412	−13
3	810	790	808	− 3
4	859	756	993	+ 16

Mean fasting pyruvic-acid levels (fig 2) did not differ between control subjects and patients with liver disease without neurological disorder Levels were raised in 5 of 29 patients in grade-I precoma, 7 of 10 in grade II coma, and 11 of 13 in grade III coma

With the development of neuropsychiatric symptoms the blood-level of both α-ketoglutaric acid and pyruvic acid tends to rise In patients with early neuropsychiatric changes, however, the scatter of results is so great that neither measurement is of practical value in the diagnosis of incipient hepatic coma

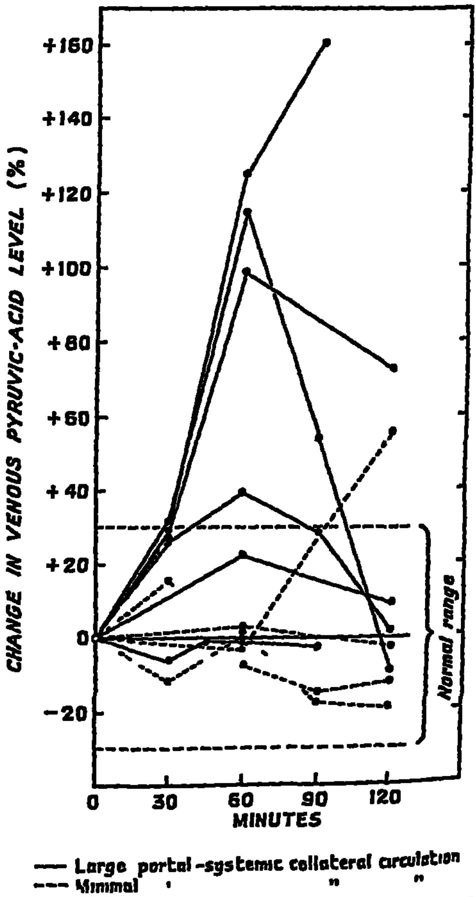

Fig 4—Change in venous pyruvic-acid levels after 3 g oral ammonium chloride (expressed as percentage of fasting value)

The peripheral venous-arterial difference of both α-ketoglutaric and pyruvic acids, in patients with liver disease, did not significantly change when there were neuropsychiatric complications (fig. 3). In particular, there was no evidence of an increased uptake of α-ketoglutaric acid by peripheral tissues in hepatic coma.

Relation of Blood Keto-acid Levels to Blood-ammonium Levels and the Effect of Ammonium Chloride

The arterial ammonium level is said to correlate more closely than the venous values with the neurological status of the patient (Bessman and Bradley 1955). Arterial ammonium levels, however, showed no significant correlation with those of venous α-ketoglutaric acid (r = 0.21, 50 observations) or venous pyruvic acid (r = 0.19, 43 observations).

The variation of fasting venous keto-acid levels over a two-hour period was studied in 4 cirrhotic patients (table II). The maximum variation of α-ketoglutaric acid from the initial value ranged from −8% to +10%, and for pyruvic acid from −13% to +16%; this is in close agreement with the observation of Segal et al. (1956) on venous pyruvic levels. We regarded an alteration of less than 30% for either acid as not significant.

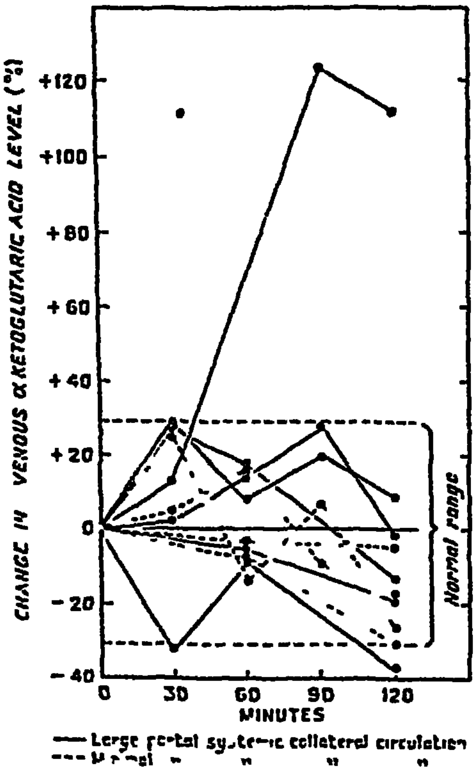

Fig. 5—Change in venous α-ketoglutaric-acid level after 3 g. oral ammonium chloride (expressed as percentage of fasting value).

In 6 patients with a large portal-collateral circulation arterial ammonium levels after 3 g. oral ammonium chloride exceeded [illegible] μg. per ml. [illegible] of these patients had [illegible] of venous pyruvic-acid levels, while 2 [illegible] change (fig. 4). 4	88	60	186	173	625	528	I	I	Chronic neuropsychiatric disorder

Thioctic Acid

Thioctic (lipoic) acid (table III) did not have a constant effect on the blood level of α-ketoglutarate in fasting subjects. The levels in patient 1 (initially normal) and in patient 4 (initially raised) did not change significantly; in patients 2 and 3 they fell slightly. Venous pyruvic-acid values fell significantly only in patient 3. This patient, the only one showing clinical improvement, was also having active treatment for bleeding œsophageal varices, and it was difficult to ascribe the benefit only to the thioctic acid.

DISCUSSION

The levels of blood keto-acids are greatly influenced by the nutrition of the patient and by vitamin-B deficiency. Glucose feeding may double the blood keto-acid level in patients in hepatic coma (Amatuzio and Nesbitt 1950). The patients we studied were fasting overnight and had all been given adequate vitamin-B supplements. Increased fasting α-ketoglutaric-acid levels in liver disease agree with the observations of Seligson et al. (1952) and Smith et al. (1953). The latter group report normal blood-pyruvic-acid values, but Seligson et al. (1952) found raised blood-pyruvate levels; precomatose patients were, however, included. In the individual patient values for either keto-acid were not sufficiently predictable to be of practical value in clinical diagnosis or in the management of hepatic coma. Levels have not hitherto been compared with the severity of the neuropsychiatric disturbance. It was interesting to find that in each neurological grade the mean level increased as the neurological state deteriorated. This indicates a progressive impairment of intermediate carbohydrate metabolism. This could be a reflection of failure of the liver to deal with a normal quantity of these metabolites or due to a general failure of intermediate metabolism so that the liver is called upon to deal with an increased load. Two important factors in the production of hepatic coma are liver-cell failure and a large portal-collateral circulation (Sherlock et al. 1954). The keto-acid levels correlated better with the severity of liver-cell failure than with the extent of the collateral circulation. Most of the comatose patients with low levels were suffering from chronic portal-systemic encephalopathy, in which shunting of portal blood into the systemic veins is of major importance and liver function is relatively good. Seligson et al. (1952) have also noted high levels of α-ketoglutaric acid in the blood of patients with acute hepatic [illegible] when liver-cell damage is the main factor. Blood ammonium reflects the shunting of portal venous blood into the systemic veins as well as the state of the liver cells (White et al. 1955). [illegible] that the blood-ammonium levels failed to correlate with the blood keto-acid levels.

Bessman and Bessman (1955) suggested that ammonium interfered with cerebral metabolism by withdrawing α-ketoglutarate from the Krebs tricarboxylic-acid cycle This cycle functions in peripheral tissues, yet there was no relationship between the venous α-ketoglutaric-acid and arterial ammonium levels, and ammonium chloride did not cause a fall in α-ketoglutaric acid levels or a contraction of the arterial venous difference of α-keto glutaric acid We confirmed the Bessmans' (1955) observation that ammonium is removed by peripheral tissues, it seems, however, that ammonium toxicity is not related to withdrawal of α-ketoglutaric acid from the tricarboxylic-acid cycle The rise of venous pyruvic-acid levels after oral ammonium chloride in some cirrhotic patients with a large portal systemic shunt suggests that in some circumstances, when a large amount of ammonium reaches the peripheral tissues, the ammonium ion interferes with intermediate carbohydrate metabolism

The rôle of thioctic (lipoic) acid in the citric-acid cycle has been fully reviewed by Ochoa (1954) Though a deficiency of the co enzyme in hepatic coma seems unlikely, it has been claimed to give encouraging results in treatment (Rauch 1954, Steigmann and Canahuati 1956) The effect in the 4 cases reported was unconvincing and extension of the trial did not seem warranted

Summary

In fasting patients with hepatic cirrhosis, mean levels of α-ketoglutaric acid in venous blood were raised, but mean levels of pyruvic acid were normal

Both levels rose progressively as the neuropsychiatric state deteriorated to hepatic coma

There was no correlation between the arterial level of ammonium and the venous level of α-ketoglutaric acid or pyruvic acid

No constant pattern in α-ketoglutaric-acid response (arterial or venous) was observed in 10 cirrhotic patients given 3 g oral ammonium chloride but in 4 of the 6 patients with a large portal systemic collateral circulation the venous pyruvic acid rose

Thioctic acid was given to 4 patients in hepatic pre coma without constant effect on the clinical state or blood keto acid level

We wish to thank Lederle Laboratories Division, Cyanamid Products Ltd, for generous supplies of thioctic acid, and the Medical Research Council for a grant for technical help Miss Y d'Almeida, B SC, and Miss J McLaren, B SC, gave valuable biochemical assistance

A COMPARISON OF THE EFFECTS OF PHENOBARBITONE AND RESERPINE IN HYPERTENSION

E H COOPER
M B Lond, M R C P
LATELY MEDICAL REGISTRAR

W I CRANSTON
M B Aberd, M R C P
LATELY ASSISTANT, MEDICAL UNIT

ST MARY'S HOSPITAL, LONDON *

THE rauwolfia alkaloid, reserpine, is now generally accepted as an effective means of treatment in many cases of essential or renal hypertension (Doyle and Smirk 1954, Locket 1955) Reserpine is known to have some sedative or tranquillising effect (Kline 1954), and the possibility has not been excluded that the hypotensive effect may be due to sedation (Tuchman et al 1954) For this reason a small controlled trial was made to compare the effects of reserpine and phenobarbitone on blood-pressure

Methods

The patients submitted to the trial were 3 men and 8 women, aged 35–62, all of whom were considered to have essential hypertension on the basis of clinical, radiological, and bacteriological findings, 7 received reserpine ('Serpasil'), phenobarbitone, and control tablets, and 5 received only reserpine and control tablets The dosage of reserpine was 0 5 mg thrice daily, and that of phenobarbitone gr $^{1}/_{2}$ thrice daily, these dosages were thought to be roughly equivalent in sedative effect The drugs and control tablets appeared identical, so that neither the patient nor the examiner knew which tablet was being

* Now in the department of the regius professor of medicine Radcliffe Infirmary, Oxford

taken and the order of taking the drugs was randomised. Each patient was treated for twelve weeks with each tablet and attended once weekly, at the same time of day each time. Blood-pressures were measured by the same person using the same sphygmomanometer each time. Blood-pressures were measured in the lying, sitting, and standing positions at each attendance.

When the results became available, it was evident that there was a considerable delay between the administration of reserpine and its effect on blood-pressure, sometimes amounting to four or five weeks. For this reason the readings during the first six weeks of each trial period were ignored, and only measurements in a "steady state" during the second six weeks were used as a basis for comparison.

Results

Blood-pressure.—For each patient the mean blood-pressure was calculated, with its standard error, for the last six weeks of each period in the standing, sitting, and lying positions. The mean pressures during the control period and the mean fall in blood-pressure in the standing position during the second six weeks of treatment with reserpine and phenobarbitone are shown in the accompanying table, from which it is evident that phenobarbitone produced a fall of blood-pressure in only 3 of the patients who received it, and over the whole group it had no significant effect on the blood-pressure, the mean fall being $\frac{2.5 \pm 4.2}{1.8 \pm 1.2}$ mm Hg. Reserpine produced a fall of blood-pressure in all the patients, and its effect was highly significant, the mean fall was $\frac{16.7 \pm 4.6}{14.3 \pm 1.5}$ mm Hg. The effects on blood-pressure in the sitting and lying positions were similar in every respect. In the sitting position the average falls of blood-pressure due to phenobarbitone and reserpine were $\frac{4.1 \pm 3.8}{1.7 \pm 2.6}$ and $\frac{19.8 \pm 4.6}{11.0 \pm 1.9}$ mm Hg respectively. Similarly the falls of blood-pressure in the lying position were $\frac{11.8 \pm 4.6}{4.7 \pm 2.6}$ and $\frac{23.2 \pm 6.2}{14.7 \pm 2.0}$ mm Hg respectively.

Weight Changes.—The weight changes varied, and though there was usually a weight gain on treatment with reserpine, this gain often persisted subsequently for more than twelve weeks. On average during the twelve weeks on phenobarbitone treatment there was no weight change, on control tablets a loss of 1/2 lb, and on reserpine a gain of 7.1 lb.

Side-effects.—3 of the patients complained of nasal blocking during treatment with reserpine, but no other symptoms were observed. There was no subjective history of depression and no objective evidence of mental retardation.

Discussion

The blood-pressure was relatively stable in each patient, as shown by the small standard error of the means during each period. This may have been due to the fact that the patients were attending regularly for some time before the period which was used for calculation, so that they became accustomed to the procedure.

Reserpine produced a significant (p<0.05) fall of diastolic blood-pressure in each of the 7 patients treated with reserpine and phenobarbitone, and a significant fall in systolic pressure in 5 of them.

Phenobarbitone caused a significant fall in systolic pressure in 3 patients and a significant fall in diastolic pressure in 2. Although the blood-pressure fell in 3 patients treated with phenobarbitone, none of these [illegible]

[illegible] phenobarbitone [illegible] the [illegible] [illegible] [illegible] postural

effect of reserpine on blood-pressure suggests that the mechanism controlling normal blood-pressure was unaffected.

Summary

The effects of phenobarbitone and reserpine on blood-pressure were compared in a small controlled trial in 7 patients with essential hypertension.

Phenobarbitone gr. 1/2 thrice daily had no significant effect on blood-pressure. Reserpine 0.5 mg. thrice daily produced a significant fall of blood-pressure in all 7 patients.

There was no postural fall of blood-pressure in patients treated with phenobarbitone or with reserpine.

We are grateful to Dr. C. D. Falconer, medical adviser to Ciba Laboratories, for supplying us with the tablets used in this trial.

POLYNEURITIS AS A CAUSE OF "AMYOTONIA CONGENITA"

RICHARD CHAMBERS
B.M. Oxfd, M.R.C.P.
FORMERLY RESIDENT MEDICAL OFFICER, THE NATIONAL HOSPITAL FOR NERVOUS DISEASES, QUEEN SQUARE, LONDON

VIOLET MACDERMOT
M.R.C.S.
FORMERLY RESIDENT OFFICER, NEUROLOGICAL AND NEURO-SURGICAL DEPARTMENTS, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

AMYOTONIA congenita appears in infancy and is characterised by muscular weakness, hypotonia, loss or depression of reflexes, and contractures.

This clinical picture may be produced by various diseases, but in the majority—about 80% in Walton's (1956) series—it is due to some form of spinal atrophy or myopathy. Walton lists thirteen causes of the syndrome, and Brandt (1950) and Lizard (1954) add many general diseases which may be associated with muscular hypotonia in infancy.

In published accounts it is repeatedly stated that partial or even complete recovery is possible from amyotonia congenita, but the possibility of recovery from the pathological processes postulated in these conditions has never been adequately explained. All of Walton's (1956) cases which improved were classed as benign congenital hypotonia (benign congenital myopathy), which he does not regard as a "true myopathy." Nattrass (1954) concluded that of his patients who recovered from myopathy, the majority had polymyositis and the remainder benign congenital myopathy.

We report here three cases in which children with amyotonia congenita improved and were shown to be suffering from polyneuritis.

Case-reports

FIRST CASE

A boy aged 7½ years was admitted to the Hospital for Sick Children, Great Ormond Street, on June 5, 1956, under the care of Dr. Paulsen [illegible] a history of inability to [illegible] He was born of a normal family with [illegible] consanguinity. [illegible] normal [illegible] he was [illegible] normal [illegible] until the age of 2 months [illegible]

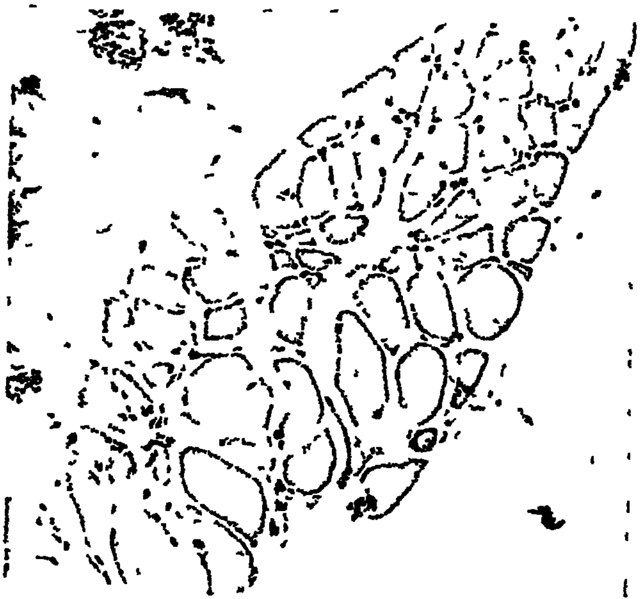

Fig 1—Case I transverse section of tibialis anterior muscle showing abnormal variation in thickness of muscle-fibres and prominence of subsarcolemmal nuclei (Hæmatoxylin and van Gieson ×154)

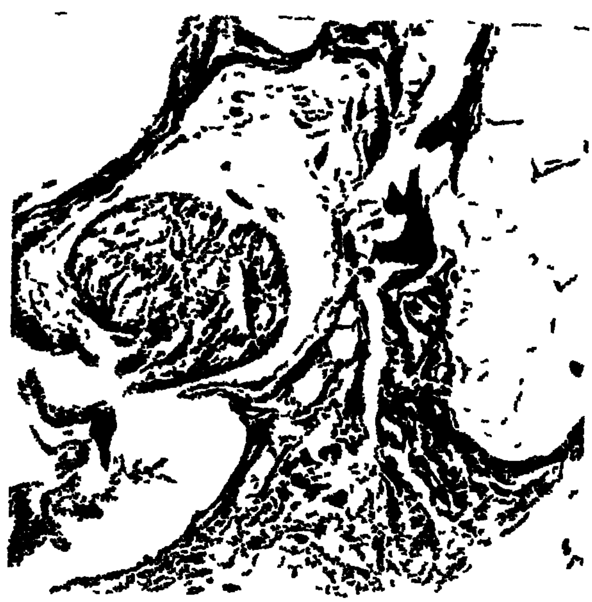

Fig 2—Case I transverse section of muscle and nerve bundle showing decreased number of myelinated fibres (Hæmatoxylin and van Gieson ×360)

weeks After this illness he continued to develop normally as regards gain in weight and mental function He had acquired full control of his sphincters at the age of 3½

After the gastro enteritis his spontaneous movements, particularly of his legs, were very slow to return and he was unduly limp Noticeable improvement was not observed until 15 months later, when he began to hold a rattle, to feed himself, and to sit with support A year later, at the age of 2½, *he could pull himself to his feet, and at the age of 4 he* began to walk, holding on to furniture

In the subsequent 3 years he learnt to write, to use his hands with considerable dexterity, and to stand unsteadily for a few seconds without support He never could raise his head when lying supine although he controlled it fairly well when erect

Apart from a thoracic scoliosis noticed at the age of 2½ years there were no other symptoms referable to his nervous or other systems He had been seen several times at Great Ormond Street and elsewhere since he was 2½ years old and was regarded as having amyotonia congenita

Examination

His mental state and speech were normal He walked only with support, on a wide base, with considerable ataxia and could stand alone unsteadily Romberg s sign was positive

He had slight asymmetry of the skull and moderate dorsal kyphoscoliosis, convex to the right He could not raise his head from the pillow

His *cranial nerves were normal except for a fine nystagmus* on full lateral gaze and weakness of his orbicularis oris muscle His sternomastoid and trapezius muscles were thin and weak His skeletal musculature was small, but there was no obvious wasting His limbs were hypotonic, and power was generally diminished in both arms and legs, more so distally and more so in the legs His trunk musculature was likewise weak Movement *of his limbs was ataxic, equally so* on both sides All his tendon reflexes were absent His abdominal reflexes were present and equal, and plantar responses flexor No sensory abnormality was discovered

He was slightly underweight (40½ lb), but no other abnormality was found

Investigations

His blood count, blood calcium, blood phosphorus, and blood-alkaline phosphatase were normal His urine was normal A radiograph *of his skull was normal* apart from slight brachycephaly and slight asymmetry Radiographs of his spine were normal except for dorsal scoliosis His intelligence quotient was 100 A sweating test was normal

His cerebrospinal fluid (C S F) was examined twice at an interval of 3 months On each occasion the pressure and dynamics were normal The protein content was 200 mg per 100 ml on the first occasion and 100 mg per 100 ml on the second An air encephalogram was normal

Electromyography (Dr A T Richardson) of his tibialis anterior muscles "*Occasional fibrillation potentials, and, on* volition, a reduced number of motor unit potentials, many of high amplitude *and long duration*"

Biopsy of tibialis anterior muscle (Dr W Blackwood) "There is abundant muscle tissue, although the fibres vary in calibre (not grossly) and the subsarcolemmal nuclei are prominent The nerve bundles contain only a few nerve-fibres (methylene blue) and few myelinated fibres (paraffin) In sections stained with methylene blue a few fibres going to nerve *endings* were *seen One of them shortly* before the nerve ending gave off an ultraterminal branch such as is seen after reinnervation The appearances suggest (1) a long-standing denervation with branching of residual nerve fibres to innervate muscle fibres other than those originally supplied, and (2) a partial sensory denervation of the muscle, because the degree of apparent loss of myelinated *nerves from the nerve bundles seems proportionately* much greater than the number of denervated muscle fibres" (figs 1 and 2)

The detailed history of this patient revealed a relatively rapid onset of the motor disability and slow recovery The clinical and laboratory findings were typical of polyneuritis, and the diagnosis was confirmed histologically by denervation atrophy with reinnervation of muscle and lesions of both motor and sensory fibres The only equivocal finding was the fine nystagmus on full lateral gaze Perhaps this was the consequence of a slight residual weakness of the *external ocular muscles, but* possibly it was due to anoxic damage sustained at birth

SECOND CASE

A boy, aged 4 years, was admitted to the National Hospital Queen Square, under the care of Dr Macdonald Critchley on July 20, 1955, with a history of weakness of the limbs since *infancy and disordered pronunciation* since he began to speak at the age of 1 year

He was adopted at the age of 3 weeks No family history and no history of pregnancy and delivery were available He had had pneumonia at 15 months and otitis media at 2 years From both these illnesses he recovered *completely* Nothing abnormal was noticed in the first few months save that he *frequently* vomited after his feeds This symptom ceased after he was weaned at 6 months

The onset of his motor disability is *difficult* to date but when he was 6 months his foster parents *first began to concern* themselves at his not sitting up and at his lack of movement It was not until *he was 18 months old that he made* much use of his limbs, at this time he began *to crawl* and to stand with support Not until he was 3 years old did he use his hands freely to manipulate his toys *In the few months before his* admission he had learnt to feed himself and could walk about [illegible] yards alone. Since he first began to speak he had also had [illegible] particular difficulty in pronouncing L, R, [illegible] and S. His [illegible] parents reported that there had been slight improvement in his movements since the age of [illegible] years. On direct questioning it was learnt that whereas he had always been [illegible] the [illegible] soles of his feet, they had in the last few months become ticklish. No other symptoms were elicited.

Examination

He was normally developed, cooperative, and very intelligent. He had a "lolling" type of dysarthria and tended to omit L and R. He could stand but walk unsupported, but his stance was unsteady, and Romberg's sign was positive. His gait was broad-based and ataxic, and he had a waddling appearance due to an exaggerated lumbar lordosis. His cranial nerves were normal.

He was flabby, and obvious wasting was present only in the small muscles of his hands. He had generalised hypotonia with moderate hyperextensibility of all the joints of his limbs. All his skeletal muscles were weak, more so distally. There was moderate ataxia in all his movements. All his tendon reflexes were absent; his abdominal reflexes were present and plantar responses flexor. He had impaired joint-position sense in his fingers and impaired two-point discrimination on his soles but no abnormality elsewhere. General examination was normal.

Investigations

His haemoglobin and urine were normal. His erythrocyte-sedimentation rate (Westergren) was [illegible] mm. in 1 hour. His c.s.f. was under normal pressure and there was no block. It contained [illegible] mg. of protein per 100 ml. but was otherwise normal.

No definite abnormality was found on electromyography of his quadriceps and tibialis anterior muscles. Biopsy of the [illegible] muscles was normal.

The history is of delay in the acquisition of movement first noticed at the age of [illegible] months, with subsequent improvement, and without other symptoms. The clinical picture of ataxia, weakness and wasting, areflexia, [illegible] sensory [illegible] associated with a raised level of protein in the c.s.f., and the history of obvious improvement strongly suggest [illegible].

[illegible] CASE

A girl, aged [illegible] years, was admitted to the Hospital for Sick Children under the care of Dr. [illegible] in [illegible] with a history of delay in walking.

She came of a healthy family with no consanguinity and no history of any nervous or other disease. The whole family [illegible] had lived in Singapore for three years before admission. Pregnancy [illegible] and [illegible] were normal and [illegible] movements vigorous. Delivery was at full term and labour was normal. The milestones were passed at the normal time up to the age of [illegible] months. She was noticed at the age of 11 months [illegible] when she sat up. She could not stand until she was [illegible] months of age and could not walk until she was [illegible]. She had full control of her sphincters at the age of [illegible] and was speaking in sentences at the age of [illegible].

From the age of [illegible] her walking very slowly improved. She was always unsteady on her legs and had a rolling gait, and easily [illegible] to the floor. At [illegible] she could walk about [illegible] yards by herself, and her usual means of progression was on [illegible]. Her parents had noticed no disorders in the use of her hands or arms.

On the voyage to England from Singapore her instability on her feet led her parents to carry her everywhere, and at the end of the voyage she was walking very much worse than before. There had been no disturbance of her general health, nor had she complained of any symptoms during this time. There had been no loss of [illegible].

This setback was largely overcome by energetic physiotherapy in [illegible] weeks in hospital. No other symptoms were elicited.

Examination

She was of normal mentality and development, and on admission she sat, she could not stand, and did not [illegible]. Her cranial nerves were normal. She had no wasting of her arms, which were hypotonic. There was slight weakness of the small hand muscles and of finger movements. She had mild ataxia on carrying out the finger-nose-finger test. There was weakness of flexion and of extension of the trunk. The muscles below the knee and the intrinsic muscles of the feet on both sides were slightly wasted, and the tendo Achillis slightly shortened. She had moderately severe weakness in both legs and could not dorsiflex or evert her feet. All her tendon reflexes and abdominal reflexes were absent and plantar responses flexor. She made errors in the appreciation of joint-position sense in the fingers and toes and in two-point discrimination in the fingers. General examination showed no other abnormality.

Investigations

Her blood count and urine were normal. A [illegible] test was normal. Radiographs of her skull, spine, and feet were normal. Her [illegible] was normal. [illegible] of the [illegible] showed [illegible] her legs, [illegible]. Her c.s.f. was [illegible] at [illegible] months. The pressure, dynamics, and [illegible] were normal except for a protein content of [illegible] mg. per 100 ml. on [illegible] occasion.

Electromyography of the tibialis anterior muscles (Dr. [illegible]) [illegible]. Fibrillation potentials [illegible]. On volition there was a reduced interference pattern of motor

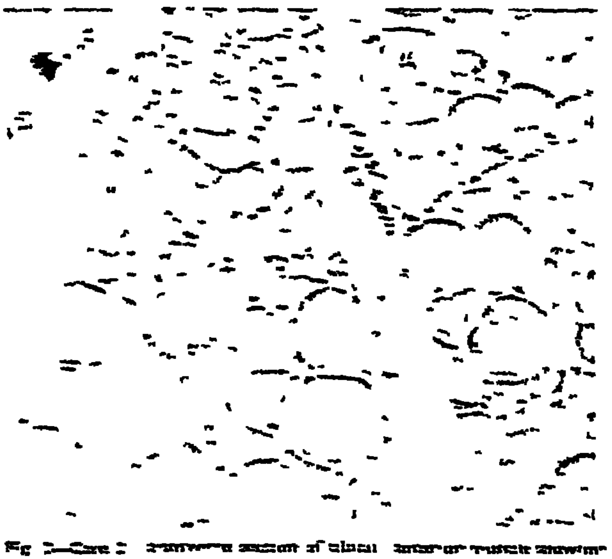

Fig. 2—Case 2: transverse section of tibialis anterior muscle showing abnormal variation in the size of muscle-fibres and prominence of subsarcolemmal nuclei. (Haematoxylin and eosin [illegible].)

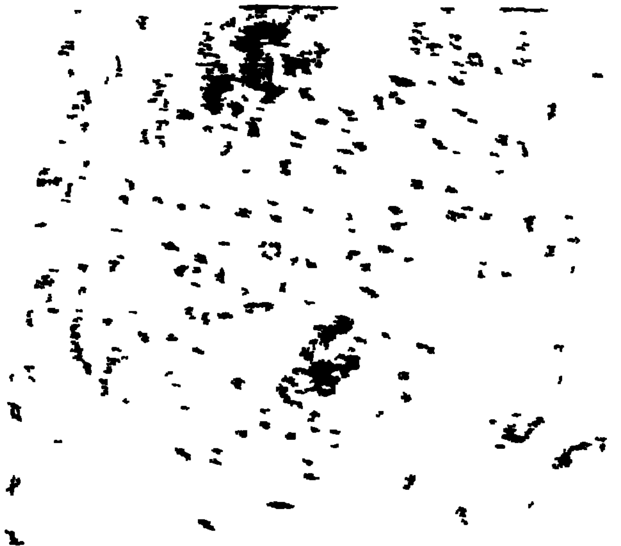

Fig. 3—Case 2: transverse section of nerve bundle showing decreased number of myelinated fibres. [illegible] are arrowed. [illegible] 210.

unit potentials of 5–10 m sec Occasional large polyphasic potentials were seen "

Biopsy of the left tibialis anterior muscle (Dr W Blackwood) "The muscle fibres show considerable variation in calibre and many groups of slender hypernucleated fibres The nerve bundles are poorly myelinated The appearances are those of denervation " (figs 3 and 4)

Follow up

3 months later, during which time her Achilles tendons had been lengthened and she had received much physiotherapy, there was no significant change in the physical signs, but she could stand and walk with support and had become more mobile

The history is of delay in the acquisition of movement, first noticed in the second 6 months of life, with subsequent slow improvement in a child who was otherwise normal

The evidence that she had polyneuritis is the clinical picture of widespread symmetrical paresis, worst distally and in the legs, muscle wasting, absent reflexes, mild sensory disturbance in the extremities, and absent flare in the triple response elicited in the extremities, with a raised C S F protein, and electromyogram and biopsy characteristic of denervation

The setback on the voyage back from Singapore to England we attribute to the interruption of physiotherapy rather than to a relapse of polyneuritis, because the symptoms were confined to the legs, sparing the trunk and arms, were not associated with any constitutional or other disturbance, and were rapidly relieved by physiotherapy

Discussion

The diagnosis of polyneuritis in these cases rests upon the clinical and laboratory evidence The history of the onset of the illness in each case is that the parents noticed a delay in the acquisition of movement without retardation of development in any other direction In case 1 detailed questioning established that the onset of the illness followed an attack of gastro enteritis, but no such information was elicited in the two other cases The course of the illness in all three cases was slow improvement The clinical picture was of widespread symmetrical lower motor-neurone paresis, worse in the legs than in the arms and more severe distally than proximally Associated with this were loss of the tendon-reflexes and, in two cases, mild but unequivocal sensory disturbance in the digits There was no muscular tenderness In all three cases the C S F was under normal pressure, there was no suggestion of a block, and the protein content was raised Denervation of muscle was shown by electromyography and by biopsy in cases 1 and 3, and damage to the peripheral sensory system by biopsy in case 1 and by absence of the flare from the triple response in case 3 All three patients were of or above average intelligence There was no sign of damage to the central nervous system No case showed disturbance of the sphincters or of general health , nor was there any skeletal or other disorder

All these patients conformed to the clinical criteria of amyotonia congenita All had been seen from time to time since the onset of their illness by competent physicians, and had been given the usual discouraging prognosis This, in two cases, had led to reluctance on the part of the local authorities to invest their limited resources of physiotherapy and education in such unpromising material Considerable correspondence was needed before the patients could benefit from these facilities The lamentable effects of neglect of physiotherapy are shown in case 3, who almost entirely lost the ability to walk as a result of being taken off her legs for 3½ weeks The importance of recognising this group of cases needs no further emphasis

The diagnosis of polyneuritis in these cases had not been seriously considered, because the clinical picture did not conform to that of acute polyneuritis in infancy (Casamajor and Alpert 1941, Andersen 1947, Brandt 1950), they were too young for a reliable sensory examination, the C S F had not been examined, and polyneuritis as a cause of amyotonia congenita is conspicuously rare in the literature

Ford's textbook (1952) and the review by Adams et al (1953) mention the possibility that amyotonia congenita is sometimes due to unrecognised polyneuritis, but they do not cite such a patient Sobel (1926), Brandt (1950), and Tizard (1954) mention polyneuritis as a possible cause to be borne in mind Bernhardt (1907) discussed two such cases and Leclerc (1907) another in which polyneuritis was the most likely diagnosis Leclerc's case was not unlike case 1 in that the symptoms were first noticed after bronchopneumonia at the age of 7 weeks and slow but steady recovery ensued

As many who have written on this topic point out, to establish an ætiological or pathological diagnosis in a case of amyotonia congenita there is need for repeated and meticulous examinations In spite of the common difficulty in differentiating between symptoms suddenly noticed and symptoms suddenly appearing, the retrospective history, as in case 1, in Leclerc's (1907) case, and in some of Nattrass's (1954) cases, may suggest an onset too rapid for a myopathy or for a " spinal atrophy " Later in the course of the illness the history of improvement is likewise a useful pointer

The main features of the paresis are its widespread distribution at an early stage and the presence of a degree of ataxia unusual in a myopathy of comparable severity We were fortunate in that our patients were old enough to be good sensory witnesses In the absence of this aid to diagnosis the triple response is the simplest test of the integrity of the peripheral sensory system

The most important single investigation is the examination of the C S F A raised protein level is an important finding with which to support the diagnosis The persistence of the increase of protein in the C S F for long periods after acute polyneuritis is well known, but the length of time in the present cases is remarkable

Electromyography and muscle biopsy usually establish the presence of denervation atrophy, and occasionally biopsy provides evidence of damage to sensory nerves Such procedures distinguish this small group of cases from the various types of spinal atrophy, myopathy, and myositis At a later stage in the illness chronic familial polyneuritis, and perhaps Friedreich's ataxia, have to be distinguished In the cases we have reported above the main points are the early onset, the improvement, the early involvement of the trunk musculature, and the raised level of protein in the C S F

As regards pathology and ætiology we have no observations to contribute beyond those already mentioned

The treatment of these patients is that of any polyneuritis—maintenance of the general health, the prevention and treatment of intercurrent illness, the prevention or correction of deformity, and training in movement Physiotherapy must be skilful and regular

The possibility that polyneuritis may closely mimic the clinical picture of the more usual causes of amyotonia congenita lends added support to the views expressed by other workers that this term should be discarded or confined to descriptive use in much the same way as the terms anæmia and glycosuria are used In particular it should be emphasised that this name implies no defined pathological process and indicates no definite prognosis

Summary

The history of the syndrome called amyotonia congenita is briefly outlined, and the fact that improvement is possible is emphasised

Three cases of amyotonia congenita are reported and shown to have been due to polyneuritis

The diagnosis of such cases is discussed, and the importance of examining the cerebrospinal fluid is emphasised

Electromyography and muscle biopsy will usually reveal denervation, and the elicitation of the triple response is suggested as a part of the sensory examination in such cases

It is important that physiotherapy be regular and skilled

The ætiological diagnosis of amyotonia congenita is briefly discussed, and the limitations of the term are explained

We wish to thank Dr Paul Sandifer and Dr Macdonald Critchley for their encouragement and advice, Dr W Blackwood for his helpful interest, Dr A T Richardson for the electromyograms, and Mr J A Mills for the photomicrographs

INCIDENCE OF COMPLICATIONS AMONG ELDERLY HOSPITAL PATIENTS

M Rang
M B Lond

HOUSE PHYSICIAN, GERIATRIC UNIT,
UNIVERSITY COLLEGE HOSPITAL, LONDON

How do old people fare in hospital? Little has been written about this, compared to the numerous accounts of the hazards facing an infant in a large hospital nursery or a soldier in a small dormitory Yet, the number of old people in this country is increasing, and more and more beds instead of being for the chronic sick, are being turned over to acute geriatric units, where the emphasis is on treatment rather than long term care The average length of stay of most of the patients in our unit is only a little longer than in the general medical wards[1] This change in the use of beds raises its own problems

Are old people less able to bear hospital discipline and procedures than the young and middle aged? Are they more liable to develop complications than younger patients? What complications occur in hospital and what proportion of patients are affected? Is it wise to admit old people for a while, so as to give their relatives a rest? Should an acutely ill patient always go to hospital where there is round-the clock nursing and medical care, or should he be nursed at home?

In an attempt to answer some of these questions, a survey was made of the complications arising in patients in our unit during twelve weeks from July to October

TABLE I—ANALYSIS OF COMPLICATIONS

—	Male	Female	Fatal	Delaying	Total
Chest infections	8	5	5	2	13
Urinary infections	1	5			6
Eye infections	2	1			3
Upper respiratory tract infections	2	1			3
Carbuncle		1			1
Confusion	1	6		1	7
Falls					
Fractured femur		1		1	1
Fractured ribs	1			1	1
Cut temple	1				1
Effusion on knee		1			1
Facial bruise	1				1
Bedsores	3	5		2	8
Superficial burn	2				2
Contractures	1	1			2
Calliper ulcer	1			1	1
Incontinence	1				1
Submandibular sialadenitis	1				1
Cerebral thrombosis		2			2
Coronary thrombosis		1	1		1
Pulmonary embolism		1	1		1
Œdema of tongue		1			1
Ammoniacal dermatitis	1				1
Surgical emphysema (from bedsore)		1			1
Total	27	33	7	8	60

Observations

The unit has two wards, one male and one female, each with 30 beds All conditions arising during the survey, which had been absent on admission and which were not clearly related to the patients' original disease, were classed as complications Control series were obtained from general acute medical wards and a geriatric half-way house

Geriatric Admissions

During the period of the survey there were 86 admissions and 82 discharges The length of time the patients had been in hospital on death or discharge is shown in the chart 45 patients developed complications (table I)—12 of whom developed more than 1 complication (table II)

TABLE II—INCIDENCE OF SERIAL COMPLICATIONS

No of complications	No of patients		
	Male	Female	Total
1	12 *(63%)*	21 *(80%)*	33 *(73%)*
2	6	3	9
3	1	2	3
Incidence of serial complications	7 *(37%)*	5 *(20%)*	12 *(27%)*

Percentages in parentheses equal incidence in each group

4 men and 2 women were admitted to give their relatives a rest from home nursing They all developed complications

Controls

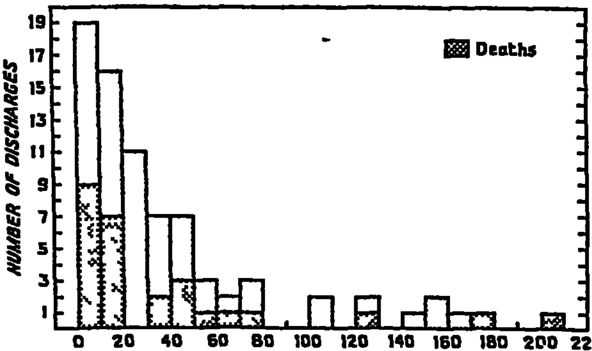
At the half-way house attached to the hospital 26 old people live The average length of stay here is measured in years, not weeks During thirteen weeks the following complications occurred

Complications	*Male*	*Female*	*Total*
Acute bronchitis	2	1	3
Bronchopneumonia		1*	1
Effusion on knee	1*		1
Acute intestinal obstruction		1*	1
Extensive bruise		1*	1
Scrotal cellulitis	1*		1
			1
	4	4	8

* Patient admitted to hospital

---

[1] Amulree (Lord), Arnold P, Polak A *Lancet* 1952 ii 191



Duration of stay of 82 patients discharged during twelve-week survey 4 of the 82 are not shown in this abridged chart They were discharged at 240 days and (by deaths) at 259, 437, and 529 days

In one general acute medical ward 30 beds were observed for twenty-two weeks Approximately half were for men and half for women Patients of all ages are admitted, but the average age is about 58 The average stay is 34 days Among the 136 patients observed, the following complications occurred

Acute bronchitis	1
Pulmonary embolism (1 death)	5
Confusion	2
Hæmatemesis	1
Fracture dislocation of head of humerus	1
Blepharitis	1
Conjunctivitis	1
Carbuncle	1
Otitis externa	1
Diabetic hypoglycæmic attacks	1
	15

Interpretation

As the duration of the survey is only slightly longer than the average length of stay in the geriatric unit (78 days) the incidence of complications cannot be related directly to admissions During the twelve week survey *on 60 beds, 60 complications* were observed, so that I complication occurred in each bed in twelve weeks This period may be called the complication interval But beds were vacant from time to time Allowing for this the complication interval =

$$\frac{\text{Number of patients} \times \text{days in hospital (4758)}}{\text{Number of complications (60)}} = \textit{79 days}$$

The complication interval in the general medical wards was 298 days, and for cases in a half-way house it was 282 days

The prospect of a patient developing a complication may be calculated indirectly The average duration of stay of geriatric patients was 72 days—very close to the complication interval (79 days) In consequence during the stay of 100 patients $\frac{72}{79} \times 100 = 91$ complications would be expected In the survey 45 patients developed 60 complications between them, so the number of patients required to develop 91 complications is $91 \times \frac{45}{60} = 68$ patients

From this it appears that 68% of patients admitted to our geriatric unit develop complications Worked out on the same basis, the incidence of complications for general medical admissions is just over 11%

Among the patients in the geriatric unit during the survey there were 30 deaths, of which 7 (23%) were due to complications The fatal complication interval may be calculated on the same principle as the simple complication interval

$$\frac{\text{Number of patients} \times \text{days in hospital}}{\text{Number of fatal complications}} = 680 \text{ days}$$

The percentage of patients developing fatal complications was 11% Thus in a geriatric unit of 80 beds 1 complication may be expected every day and 3 deaths from complications each month

Discussion

It is calculated that 2 out of 3 patients admitted to a geriatric unit develop 1 or more complications and that 1 patient in 10 dies of a condition acquired in hospital

The complication interval is roughly four times shorter in an acute geriatric unit than in either a half way house or an acute medical ward In each geriatric bed 1 complication occurs on average every 11 3 weeks

Of the 67 women in the geriatric ward 26 (39%) developed complications and of 74 men 19 (26%)—i e, women are affected more commonly than men in the ratio of 3 2 However the proportion of men that have a further complication is approximately twice as great (table II)

Age, in patients over sixty five, does not seem to affect the incidence of complications, *for the average age* of patients with and without complications was the same

Of 60 complications, 26 were due to infection, including 13 chest infections of which *5* were *fatal* *The chest infec*tions were unlikely to be due to seasonal exacerbations of chronic bronchitis, for the survey was made between July and October Four out of five urinary infections in women followed catheterisation In these patients "*catheter fever*" and pyuria developed after urine (sterile on culture) had been withdrawn This cannot be blamed entirely on the nurse's technique, for the same nurses working in other hospital departments do not introduce infection

12 complications were due to *falls* or to confusion These are classed together because I think that they are partly due to the same thing Taking a slightly demented old person out of his own home and putting him in a large ward, expecting him to climb in *and out of a hospital bed,* subjecting him to a routine that is strange and at times alarming, and asking him to try to walk with few and unfamiliar hand holds, puts a big *strain on* his ability to remain upright and sensible

The patients who were admitted to give their relatives a rest all developed complications

The survey is *not* large enough to show *all the forms* that complications take, nor the frequency of each The interval between admission and the onset of complications varied greatly and did not appear to be significant

Summary

It is calculated that two out of every three patients admitted *to* a geriatric unit develop conditions from which they were free on admission In a general medical ward only one patient in ten develops complications

The complication interval (the time between complications for *any* geriatric bed) was roughly eleven weeks—four times shorter than in either general medical wards or a half-way house

A quarter of all deaths in this unit were due to complications

Women were more commonly affected than men in the ratio of 3 2, but men more commonly had several complications

Nearly half the complications were due to infection

I thank Lord Amulree for his help and encouragement in writing this paper

LATENT HÆMOLYSIS IN RHEUMATOID ARTHRITIS *

P C McCrea
M D Belf

ASSISTANT PATHOLOGIST, HARROGATE GROUP OF HOSPITALS

THE rate of red blood cell destruction is increased in many diseases in which a hæmolytic process is not the predominant factor—e g, cirrhosis of the liver (Chaplin and Mollison 1953) and uræmia (Emerson 1948, Chaplin and Mollison 1953) In some of these conditions a hæmolytic state may be inferred from the results of routine laboratory tests Latent hæmolysis may be present in other conditions in which the serum bilirubin level is within normal limits, and in which reticulocyte counts are normal or only *slightly increased* *In such* cases red cell life span must be measured directly to demonstrate a hæmolytic mechanism

Mollison and Patterson (1949) transfused sensitised red cells to 2 patients with rheumatoid arthritis *and found* that in both cases the transfused cells were *eliminated* at an increased rate The experiment was repeated using unsensitised cells and in 1 case the transfused cells were eliminated in about fifty days In 1 severe case of rheumatoid arthritis investigated by Brown et al (1944) transfused cells were not destroyed abnormally quickly When the present investigation was started no further report on red-cell life span in rheumatoid arthritis had appeared Since that time Bunim (1954), using cells tagged with radioactive chromium, and Freireich et al (1954) and Alexander et al (1956), using the Ashby technique, have reported that the life span of normal red cells in the circulation of rheumatoid patients is diminished

---

* Based on a *thesis for the degree of* M D in the Queen's University of Belfast

Material and Methods

In the present investigation the life span of normal red cells in the circulation of 15 patients with anæmia and rheumatoid arthritis was measured The effect of intravenous iron therapy on the anæmia was studied in 7 of the 15 cases Marrow-iron examination, which is a means of distinguishing the iron-deficient from the non-iron-deficient patient (Hutchinson 1953), was carried out in each of the 7 cases before blood-transfusion or the administration of iron The effect of intravenous iron therapy was studied over a test period of about a month, either before the start of or after the conclusion of the transfusion experiment in each case About one gramme of an iron preparation for intravenous use (saccharated oxide of iron in colloidal solution, either ‘Ivron’ or ‘Ferrivenin’ containing 20 mg colloidal iron per ml) was administered in from six to ten injections over a period of eight to ten days

The 15 patients examined were inpatients at the Royal Bath and White Hart Hospitals, Harrogate 13 were classified as having “very” active disease, the remaining 2 had “moderately” active disease In classification the following factors were considered the degree of joint pain and tenderness, the presence of general constitutional symptoms and the erythrocyte-sedimentation rate (E S R)

Red-cell life span was measured by Dacie and Mollison's (1943) modification of Ashby's technique Anti-M sera in the form of powdered globulin (Lederle) were used for differential agglutination (Ebert and Emerson 1946, Mollison 1951a) Pre transfusion (‘blank”) counts with these sera varied from 3000 cells per c mm to 10,000 cells per c mm All recipients were of blood group M or MN The cells from 800–1200 ml. of blood from normal donors (group N) were transfused in each case either as whole blood or in the form of a concentrated red cell suspension The blood had been stored in acid citrate-dextrose solution for six days or less in 12 cases, but in 3 instances was up to ten days old Estimations of surviving transfused cells were made twenty-four to forty-eight hours after transfusion, again after a few days, and thereafter at convenient intervals For the first post transfusion estimation 4000 cells were counted, afterwards 2000 cells were counted until near the end of the follow up period when cells were relatively scarce and 1000 cells were counted

Red-cell-survival Experiments

The figures obtained for red-cell survival were plotted graphically against time In the single case in which the number of transfused cells diminished steadily with time, the mean red cell life span was estimated by fitting a straight line to the points by inspection and noting the point at which the line cut the time axis In the remaining cases, in which the slopes of elimination were curvilinear, the mean red cell life span was calculated by the simple method devised by Dornhorst (1951) and described by Mollison (1951b) The observed values for transfused red cells were each multiplied by $\frac{120}{120-t}$ where t is the number of days after transfusion These corrected values were then plotted graphically against time and the area under the curve was measured between 0 and 120 days This area was then divided by the initial height to give the mean cell life

TABLE I—RED CELL LIFE SPAN ESTIMATIONS

Case no	Age (yr)	Sex	Disease activity before transfusion	Hb (g per 100 ml)	P C V (%)	M C H C (%)	Reticulocytes (%) (max count)	Serum bilirubin (mg per 100 ml)	Mean red cell life span (days)
1	62	M	Mod	10 1	37	27	1 2	0 2	93
2	56	F	− − −	9 0	34	26	2 8	0 4	60
3	58	F	+ − −	9 3	34	27	1 8	0 2	30
4	56	F	− − +	9 0	33	27	1 3	0 2	61
5	58	F	− + −	9 0	33	27	1 2	0 4	70
6	55	F	− − −	10 2	36	28	1 7	0 2	60

15	65	F	+ + −	11 5	39	30	1 2	0 2	98

Other Tests

Reticulocytes were counted, antiglobulin reactions were carried out, and cold-agglutination titres were measured using the methods described by Dacie (1950) Serum-bilirubin and fæcal-urobilinogen estimations were made by the methods of King (1951) Red-cell osmotic fragility was determined by the technique of Creed (1938) Marrow punctures were performed in the manubrium or first or second parts of the body of the sternum under local anæsthesia Histological sections prepared from aspirated marrow fragments were stained for iron using the method described by Hutchinson (1953) With regard to iron content the marrows were roughly classified as showing “none,” “a small amount,” “a moderate amount,” or “a large amount” of stainable iron

Results

The results are given in table I It is generally agreed that the normal life span of the red cell is 100–120 days (Callender et al 1945, 1947, Mollison 1947)

In 5 of the 15 cases the red cell life span was ninety days or more Of these patients, 2 (cases 7 and 8) showed distinct clinical improvement after transfusion In 2 further patients (cases 1 and 11) there was evidence of iron deficiency in that no stainable marrow iron was demonstrable in either case and 1 (case 11) responded to iron therapy In these 2 cases disease activity varied from moderate to slight The remaining patient (case 15) had very active arthritis initially, her condition improved somewhat after transfusion, but the disease remained moderately active throughout the period of the transfusion experiment

The rate of red cell destruction was increased in 10 of the 15 cases examined These 10 patients had very active arthritis The rate of destruction varied from about two to four times normal In case 13 the rate of destruction was measured twice and each time was found to be about four times normal In this case the reticulocyte count was 3 5% and the serum-bilirubin level was at the upper limit of normal In the remaining patients, with 1 exception, the serum bilirubin levels were within normal limits and reticulocytes were 2% or less The exception was case 2, in which a reticulocyte-count of 2 8% was found once In 6 cases in which fæcal urobilinogen was estimated no excess was found Red cell osmotic fragility was normal in 6 cases in which the test was carried out

TABLE II—RESPONSE TO INTRAVENOUS IRON RELATED TO RED CELL LIFE SPAN

Case no	Sex	Marrow iron (amount)	Response to iron therapy *	Red cell life-span (days)
1	M	None	+	93
2	F	Large	–	60
3	F	Mod	–	30
4	F	Large	–	61
5	F	Small	–	70
6	F	Mod	–	60
7	F	Mod	–	90

* Increase in Hb level of 2 g or more per 100 ml

The response to iron therapy is related to red cell life-span in table II In assessing the effect of intravenous iron therapy, an increase in hæmoglobin of 2 g per 100 ml or more was arbitrarily taken as indicating a response (Coleman et al 1955) In 5 patients (cases 2–6) stainable iron was demonstrated in the bone-marrow, there was no response to intravenous iron therapy, and red-cell life span was diminished In case 7 the marrow contained iron, there was no response to iron therapy, but red cell life span was diminished little if at all This patient had improved clinically after blood transfusion In case 1 iron deficiency was a factor in the production of anæmia, as the absence of marrow iron and the response to iron therapy indicated, disease activity varied from moderate to slight throughout the period of observation and red cell life span was only slightly reduced

Deductions from Mean Red-cell Life-span

In cases where the red-cell life-span was normal or only slightly reduced, the anæmia arose from inefficient hæmoglobin production by the bone marrow due to iron deficiency, marrow dysfunction, or a combination of these two factors In some instances there was evidence of spontaneous improvement in anæmia

In case 8, for example, the packed cell volume before transfusion was 30% A week after transfusion the packed-cell volume was 36%, eight weeks afterwards it was 40%, and about twelve weeks afterwards it was 37%

In view of the obvious difficulties when marrow output is not steady throughout the period of observation, no attempt has been made to correlate life span and marrow-red-cell output in these 5 cases

When mean red cell life is reduced, the production of red cells needed to maintain a steady output is related to normal production by the expression

$$\frac{\text{Observed red cell count}}{\text{Normal red cell count}} \times \frac{\text{Normal mean red cell life}}{\text{Observed mean red-cell life}}$$

(Chaplin and Mollison 1953) For the purpose of this calculation, the normal red-cell count was taken to be 5,000,000 per c mm This figure is said to be a fair average, irrespective of sex (Whitby and Britton 1953)

Thus marrow output was found to be about one and a third times to twice normal in 8 of the 10 cases In the remaining 2 patients, red-cell output was calculated to be between three and four times the normal (table III) In making these calculations, it was assumed that red cell production was steady at the time when observations began (Chaplin and Mollison 1953)

Although the red-cell output was found to be increased in all 10 cases, the red cells produced were deficient in hæmoglobin as shown by lowering of the mean corpuscular hæmoglobin concentration

TABLE III—CALCULATED RED CELL OUTPUT IN CASES WITH A DIMINISHED RED CELL LIFE SPAN

Case no	Mean red cell life span (days)	Red cell production (ratio to normal)
2	60	1 6 1
3	30	3 5 1
4	61	1 5 1
5	70	1 3 1
6	60	1 6 1
9	40	2 0 1
10	65	1 7 1
12	54	1 6 1
13	(a) 28	
	(b) 32	3 5 1
14	70	1 5 1

Discussion

Latent hæmolysis, demonstrated by abnormally short survival-time of normal red cells, is a factor in the production of anæmia in certain cases of active arthritis The results of the present study agree with those reported by Mollison and Patterson (1949), Freireich et al (1954) and Alexander et al (1956) Evidence that there is an intrinsic red cell defect in rheumatoid patients is described by Bunim (1954), who found in a single case that red cells from a rheumatoid patient had an abnormally short life span in the circulation of a normal individual Freireich et al (1954), however, reported that red cells from rheumatoid donors survived normally in normal subjects in the few cases which they studied Alexander et al (1956) state that red cells from rheumatoid donors survive longer in rheumatoid recipients than do cells from healthy donors They suggest that this may be due to some special characteristic of the red cells from rheumatoid donors Mollison (1956), however, points out that this longer survival-time of rheumatoid cells is not surprising as red cells taken from any patient with a hæmolytic process are a selected population compared with red cells from a normal donor, and their survival is expected to be better Alexander et al further observed that the administration of corticotrophin in doses sufficient to control the clinical signs of the disease did not prolong the survival-time of normal red cells in rheumatoid patients In the present study corticotrophin was not given to any patient, but red cell life span was reduced little, if at all, in patients in whom sustained clinical improvement took place after transfusion

An increased rate of red-cell destruction has been described in the active phase of rheumatic fever (Reinhold 1954) and in nephritis (Chaplin and Mollison 1953) Hæmolysis in association with acute disseminated lupus erythematosis has been reported (Michael et al 1951, Dubois 1952) Hæmolytic anæmia is a feature of thrombotic thrombocytopenic purpura (Muirhead et al 1948, Dacie 1954a), and hæmolysis in association with periarteritis nodosa has been described (Dameshek and Rosenthal 1951) These diseases have been included by one worker or another in the "collagen disease" group, but, although fibrinoid necrosis is common to them all, it is unlikely that they have a common ætiology (Duthie 1954)

Compensatory Erythropoiesis

The bone-marrow in uncomplicated hæmolytic disease is capable of producing about six to seven times the normal amount of hæmoglobin (Crosby and Akeroyd 1952) In the present 10 cases in which hæmolysis was shown, the calculated red cell output was in most cases one and a third times to twice normal Myeloid erythroid ratios, determined in 5 of these 10 cases, varied from 1 8 1 to 4 1, and sections prepared from aspirated marrow showed normal cellularity Thus the bone marrow response to hæmolysis in these cases of arthritis was less than would be expected if marrow function were normal Hæmolysis in these cases of arthritis was associated with the production of red cells which were deficient in hæmoglobin as shown by a low mean corpuscular hæmoglobin concentration The exact nature of this defect in hæmoglobin synthesis is unknown It is not apparently due to lack of iron, as marrow iron stores were demonstrated and intravenous iron therapy failed to correct the deficiency in certain cases in the present study (table II) The diminished life span with slight increase in marrow output in these cases is somewhat similar to the pattern of anæmia in hepatic cirrhosis (Chaplin and Mollison 1953) Freireich et al (1954), using radioactive tracer techniques, estimated that iron utilisation and red cell production were normal in cases of rheumatoid arthritis in which the red cell life span was diminished Bunim (1954) agrees that anæmia in rheumatoid arthritis results, in certain cases at least, from increased blood destruction without adequate compensatory production The results of the present study agree generally with the observations of Bunim (1954) and Freireich et al (1954)

Reticulocytes, Bile Pigment, Metabolism, &c

The laboratory tests which usually indicate the presence of hæmolysis were negative in the present cases Reticulocyte counts greater than 2% were found in only 2 cases, serum-bilirubin levels were within normal limits in all 10 cases, and fæcal urobilinogen levels were not excessive in the 6 cases examined The osmotic fragility of the red cells, measured by a routine laboratory method, was normal in the 6 cases investigated Normal reticulocyte counts and serum-bilirubin levels have been reported in latent hæmolytic states associated with malignant and infective conditions (Brown 1950) and cases of leukæmia and lymphoma (Ross et al 1951) Dacie (1954b) states that serum bilirubin and fæcal urobilinogen levels are unreliable as evidence for the presence of hæmolysis in a mild hæmolytic state In the present cases, although studies of bile pigment metabolism and reticulocytes did not suggest that hæmolysis was taking place, direct measurement of red-cell life span demonstrated the existence of a hæmolytic mechanism

Serology

In the present cases direct and indirect antiglobulin reactions were negative and cold agglutination titres were within the normal range The direct anti-globulin test was negative in the 2 cases of rheumatoid arthritis investigated by Mollison and Patterson (1949), but Dacie (1954c) mentions a type of " non specific " positive anti-globulin reaction in rheumatoid patients Ball (1952) found positive sheep cell agglutination tests in a large number of patients with rheumatoid arthritis and in certain cases of acute disseminated lupus erythematosis In view of this finding he felt that this agglutinating factor might be an auto antibody, but he was unable to obtain a positive anti-globulin test in the few cases of arthritis investigated The possibility that an underlying immunological mechanism is a factor in the production of collagen diseases is suggested by the work of Glynn and Holborrow (1952a and b), who have shown that in animals injection of a polysaccharide-streptococcus vaccine led to the production of specific antibodies to the homologous polysaccharide Theoretically an inflammatory reaction in connective tissue might possibly result from union of antibodies of this type with the polysaccharide of ground substance Duthie (1954) points out, however, that so far there is no direct evidence for the presence of antibodies of this type in human disease

Factors Possibly Influencing the Increased Rate of Red cell Destruction

The curvilinear slopes of elimination of the transfused cells suggest that an extracorpuscular factor is responsible for hæmolysis in these cases of rheumatoid arthritis Intravascular aggregation of red cells has been observed in the conjunctival vessels of patients with rheumatoid arthritis (Laine and Zilliacus 1950) This pathological change in blood flow—" sludging " (Knisely et al 1947)—has been described in various infective and malignant conditions as well as in blood disorders (Knisely et al 1947, Laine and Zilliacus 1950) Bloch and Powell (1952) consider that this type of intravascular aggregation is caused by a substance adherent to the red cells which might cause red-cell agglutination and make the cells susceptible to phagocytosis and consequently to hæmolysis Wasastjerna et al (1954), however, consider that this " sludging " factor is concerned more with rouleaux formation than hæmagglutination Miller and Whittington (1942) state that the plasma viscosity can be taken as an index of the power of the plasma to cause red-cell aggregation and rouleaux formation Plasma viscosity, like the erythrocyte sedimentation rate, is a non-specific response, affected by alterations in plasma-proteins and very little by the non-protein constituents (Eastham 1954) The effect of increased plasma viscosity on blood destruction in rheumatoid arthritis is not known, but in the present study persistently high plasma viscosity levels were found in cases in which there was a diminished red-cell life span

Kellgren (1952) has suggested that peptides liberated from disruption of the collagen polysaccharide complex may be responsible for the toxic and inflammatory features of rheumatoid arthritis There is no direct evidence for this hypothesis, but toxic metabolites may possibly be responsible for hæmolysis in rheumatoid arthritis , substances of this type may be factors in the causation of hæmolysis associated with uræmia, liver disease, and carcinomatosis (Dacie 1954d) In these disorders gross morphological abnormalities of the red cells are sometimes seen—a fact which Dacie (1954d) considers a further possible indication of a toxic factor Apart from hypochromia and slight anisocytosis and poikilocytosis, no morphological abnormalities have been detected in the peripheral blood of rheumatoid patients

Conclusions

In some cases of active rheumatoid arthritis an increased rate of red cell destruction is a factor in the production of anæmia

The hæmolysis is insufficient to cause anæmia in patients whose bone-marrows are uninhibited, and inadequate compensatory red cell production by the bone marrow apparently plays a part in the causation of anæmia In rheumatoid arthritis hæmolysis is often associated with the production of red cells which are deficient in hæmoglobin—a deficiency which in the present study was not corrected by intravenous iron therapy

The presence of hæmolysis in these cases could not have been inferred from the results of routine laboratory tests Direct measurement of red cell life span was necessary to demonstrate the existence of a hæmolytic mechanism

The curvilinear slopes of elimination, when the red-cell life span estimations are plotted graphically, suggests that an extracorpuscular factor causing random destruction of cells, irrespective of their ages, is responsible for hæmolysis In the absence of any identifiable immune mechanism the exact cause is unknown, but a diminished life span seems to be associated with pronounced disease activity When sustained clinical improvement takes place or disease activity is only moderate or slight, red-cell life span is diminished little if at all

I am indebted to Dr J V Wilson for much willing help and encouragement , Dr P L Mollison for advice , Dr J J R Duthie and Dr I M P Dawson for discussion and criticism , Dr J Shone and Dr S R Gloyne, of the Regional Blood-Transfusion Centre, Leeds, for supplying the blood for the experiments , the physicians of the Royal Bath Hospital, Harrogate, for allowing me to investigate patients under their care, and other help , and members of the laboratory and nursing staffs of the Harrogate group of hospitals for much valuable assistance

POST-GASTRECTOMY STEATORRHŒA AND PATCHY JEJUNAL ATROPHY

J W PAULLEY
M D Lond , M R C P

F A FAIRWEATHER
M B Lond

A LEEMING
M B St And

From the Ipswich Hospitals

CHRONIC inflammatory changes and atrophy of the jejunal mucosa associated with idiopathic steatorrhœa have been reported by one of us (Paulley 1952a and b, 1954) This observation was contrary to the current teaching that there were no abnormal changes in sprue or steatorrhœa—a concept dating from Thaysen's (1932) monograph Since 1954 further cases here, and unpublished data from G D Hadley and M Shiner in this country and F Gardner in the U S A (personal communications) have confirmed these changes

For some years the hypothesis has been entertained (J W P) that those cases of post gastrectomy syndrome in which steatorrhœa develops and the patient loses weight may have been latent cases of idiopathic steatorrhœa before operation—the supposition being that gastrectomy is provocative in predisposed subjects by causing unaccustomed conditions in the upper intestine To test this hypothesis, for the past year wedges of jejunal mucosa have been taken by our surgical colleagues during gastrectomy A possible correlation between the state of the mucosa and the patient's subsequent course is being sought To date, of 61 patients submitted to gastrectomy, 5 had abnormal mucosa Of these 5, the abnormality was gross in 2, both of whom, when traced, were found to have steatorrhœa, to be under weight, and to be dissatisfied , 1 gave a history of loose pale foul stools for a year or more before operation, and the other was said to have had colitis ten years before, and had had a high random fæcal fat two years before This work, which is still proceeding, may explain part of the 10% failure-rate after gastrectomy

Case-record

A man, aged 51, was admitted on June 18, 1956, complaining of variable pains, increasing weakness, and pale foul diarrhœa He was depressed, pigmented, and emaciated (body weight 5st 5 lb), with blue sclerotics He had had an enormous appetite since gastrectomy two years before

The past history, obtained from the patient and his wife and brother, was as follows He was the youngest of three brothers and had fragilitas ossium His mother made a fuss of him because of his numerous fractures, and he was devoted to her , his father was an alcoholic His mother told his wife that he had always had a weak stomach, and his wife described attacks of pale diarrhœa intermittently since she married him in 1935 , he had lost much time from work He said he first had " colitis " in 1920 He was never quarrelsome and would avoid rows at any cost His brother, when asked if he was soft hearted, said " he would give himself away " He added that the patient had dwelt on his pains and illnesses all his life When his mother died in 1941 of cancer, the bottom fell out of his life, and he became depressed thinking he had cancer of the bowel Later he thought he had cancer of the throat and of the brain To the time of his death his belief that he had cancer was never dispelled In 1950 he attempted suicide by cutting his wrist , previously he had tried to poison himself, was later admitted to hospital with anæmia and melæna, after treatment was transferred to a mental hospital, and remained under outpatient psychiatric observation for the next five years He had had no sexual relations with his wife since 1940 for fear that " she should catch cancer "

In 1952 he sought surgical advice for a suspected duodenal ulcer In 1954 he saw the same surgeon, who performed an anterocolic Polya partial gastrectomy , only scarring was found He then weighed 9 st 11 lb Almost at once he began to lose weight, and nine months after his gastrectomy he weighed 7 st 13 lb , after fifteen months he weighed 7 st 3 lb Eighteen months after gastrectomy, cholecystectomy was done because of persistent pain At laparotomy gall bladder adhesions were found In February, 1956, his weight had fallen to 6 st 12 lb Steatorrhœa was suspected at the time of cholecystectomy and was confirmed in June, 1956, when a casual fæcal fat reading was 50 9 g per 100 g total fat, and a fat balance showed only 70% absorption Radiography after a barium meal showed coarse folds and spattering of barium in the small bowel

Dr Shiner kindly carried out jejunal biopsy (Shiner 19[illegible]) To our surprise the specimen did not show the expected

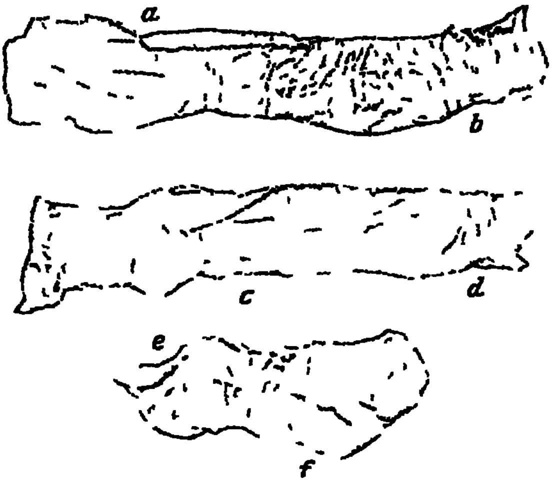

Fig 1—Jejunum, showing normal and atrophic areas

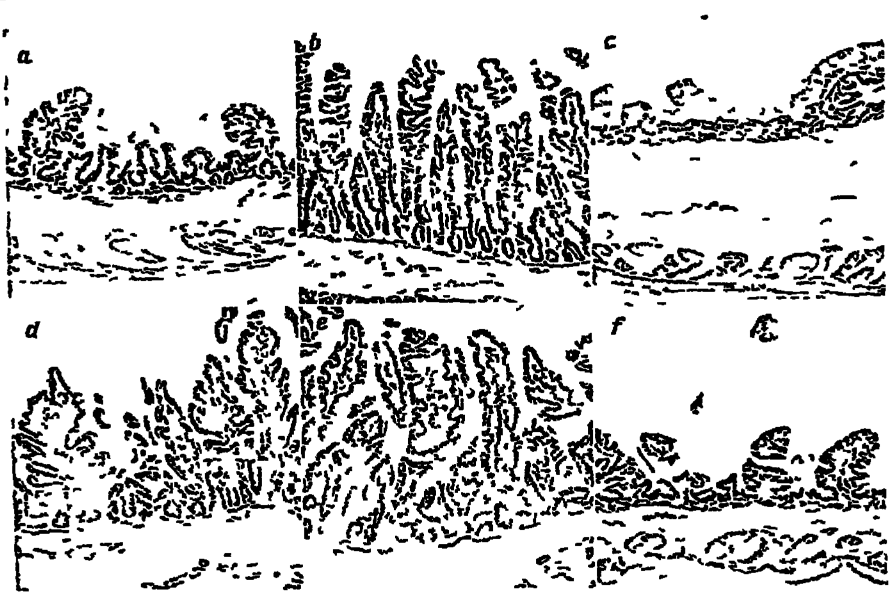

Fig 2—Microscopic appearances of jejunal mucosa (sites shown in fig 1) (*a*) atrophy, (*b*) normal, (*c*) gross atrophy (*d*) irregular villi, moderately abnormal, (*e*) somewhat irregular villi, moderately abnormal (*f*) gross atrophy

grossly abnormal changes of cellular infiltration and atrophy It was considered to be within normal limits

Despite every effort with gluten free diet, steroids, antibiotics, and modified insulin shock the patient failed to respond and died from terminal pulmonary embolism Permission for necropsy was obtained and the gut was preserved in formal saline shortly after death

Necropsy

The stomach was atrophic and the duodenum and stoma were normal The small gut was 15 ft long, everywhere its wall was thin. In the proximal 18 in the mucosa showed rugæ, though not so closely set as normal, to touch it had the normal velvety feel Below this there were many areas 6–12 in long where the mucosa appeared to be completely smooth (fig 1) and was not velvety to touch Toward the ileocæcal valve more normal mucosa was found The large intestine showed somewhat similar changes There was no ulceration The pancreas, liver, and suprarenals were normal

Microscopy confirmed gross mucosal atrophy in the areas macroscopically atrophic, and a near normal mucosa in the other areas, but the spacing, shape and size of the villi in some of these areas were irregular (fig 2)

Discussion

This man presented as a case of post gastrectomy steatorrhœa and malnutrition, but he and witnesses told of symptoms typical of steatorrhœa for many years before his operation, and he had shown emotional and personality disorder, which is common in steatorrhœa (Paulley 1949, 1952a and b, 1954) Gastrectomy precipitated a phase of gross malnutrition and steatorrhœa culminating in his death When jejunal biopsy was done there was little doubt in our minds that this was a case of idiopathic steatorrhœa aggravated by gastrectomy The almost normal mucosa was a complete surprise and quite counter to our experience and that of others in idiopathic steatorrhœa It seemed that either the diagnosis was wrong or the mucosal changes were patchy, and that we had failed to strike an abnormal area, although we had taken six specimens from different points to $1^1/_2$ feet below the stoma Shortly afterwards the case was discussed with Dr N Buyssens, of Antwerp, who said that he had seen patchy intestinal atrophy in 4 patients 1 of whom had proven idiopathic steatorrhœa, and the others malnutrition possibly with steatorrhœa

Probably our failure to obtain a biopsy specimen from an atrophic area was due to the smoothness of the mucosa rather than a failure of the tube to reach the right place The extreme thinness of the wall in the atrophic areas underlines the importance of not exceeding the negative suction pressure of –5 mm Hg recommended by Shiner to avoid perforation It now seems that a normal jejunal biopsy is not entirely dependable

Summary

Early results support the hypothesis that post-gastrectomy steatorrhœa is influenced by the state of the jejunal mucosa before operation Evidence so far suggests that surgeons should beware of gastrectomy in patients with a history of bowel looseness Jejunal biopsy may prove a useful screening measure before gastrectomy

A case is described of post-gastrectomy syndrome with steatorrhœa and malnutrition in a patient with a convincing history of intermittent steatorrhœa for many years before gastrectomy Jejunal biopsy was normal Necropsy revealed areas of gross atrophy of the intestinal mucosa separated by relatively normal areas

A negative jejunal biopsy may be misleading

On no account should excessive suction be applied during tube biopsy

We are most grateful to Mr A R Hill, Mr G F Langley, Mr R S Monro, and Mr P B Counsell for their help and also to A C Thackray, of the Middlesex Hospital, for the photomicrographs

TREATMENT OF GLUTETHIMIDE POISONING

WITH BEMEGRIDE AND AMIPHENAZOLE

N R Rowell
M B Durh, D C H
MEDICAL REGISTRAR, ROYAL VICTORIA INFIRMARY,
NEWCASTLE UPON TYNE

GLUTETHIMIDE (α-phenyl-α ethyl-glutarimide, ‘Doriden’) has recently been introduced as a non-barbiturate hypnotic The usual dose of 0 25 to 0 5 g (1 to 2 tablets) gives five to eight hours' sleep The tablets disintegrate rapidly and the patient usually falls asleep in fifteen to thirty minutes Side effects are few Occasional nausea and rashes have been reported Lane (1955) found no alteration in the blood picture, in the urine, or in the thymol-turbidity and cephalin flocculation tests resulting from long continued administration of nightly doses of 1 0 g One of the advantages of glutethimide in normal doses seems to be the absence of respiratory depression

There have been few reports of poisoning Gerster et al (1955) described the case of a soldier aged 20 who took 60 tablets (15 g) in an attempt to commit suicide He was treated with picrotoxin, prophylactic antibiotics, and intravenous fluids, and recovered Two cases treated with bemegride (‘Megimide’) and amiphenazole (‘Daptazole’) have been reported by von Planta and Klingler (1956) The first patient, a man of 29, had taken 20 tablets, the second, a woman of 23, had taken 22 tablets, and both recovered In view of the need for information on the effect of bemegride and amiphenazole on coma other than that due to barbiturate (*Lancet* 1956), I report a further case

Case-report

A married woman aged 38 was admitted in coma having taken 40 glutethimide tablets (10 g) and 16 aspirin tablets (4 8 g) fourteen hours previously On admission she was unconscious with widely dilated pupils (which did not react to light), a divergent strabismus, and absent corneal reflexes All limbs were flaccid with absent reflexes The plantar responses were not obtained and there were no withdrawal reflexes She was not cyanosed and the peripheral circulation was good Respirations were moderately deep, the rate being 12 per min , the pulse rate was 115 per min , blood pressure 120/90 mm Hg, temperature 98°F There were no abnormal signs in the heart, chest, or abdomen Soon after admission she had an attack of laryngeal spasm with carpo-pedal spasm, resembling classical tetany and lasting about two minutes

Gastric lavage was done but no tablets were returned in the washings Prophylactic penicillin was given and glucose-saline infused 225 mg (15 mg in 1 ml) amiphenazole was given intravenously in the course of twenty minutes, with increase in the depth and rate of respiration (20 a minute) 4 ml (12 mg) picrotoxin was given with no effect

Three hours later her condition was unchanged , spasms were occuring every five to ten minutes Treatment with bemegride and amiphenazole was started, 50 mg bemegride and 15 mg amiphenazole being introduced into the tubing of the drip about every three minutes In one and three quarter hours, after a total of 750 mg bemegride and 225 mg amiphenazole had been given, the patient moved her right arm slightly and the knee jerks were just obtainable During this period, she continued to have intermittent tetanic spasms of all limbs Chvostek's and Trousseau's signs were absent , the blood calcium was normal (9 8 mg per 100 ml , diffusible 4 7 mg) , there was no alkalosis (indeed, there was acidosis—alkali reserve 45 3 ml CO_2 per 100 ml plasma) , and intravenous calcium gluconate had no effect There was also intermittent fine tremor of the hands The spasms continued during the course of the next three hours 200 mg bemegride was then given in twelve minutes , this increased the frequency of the spasms After an interval, 60 mg amiphenazole was given in 12 minutes, and there was no increase in spasms 200 mg bemegride and 60 mg amiphenazole were then given together over twelve minutes with increase in the frequency of the spasms and in the activity of the knee jerks

Twelve hours later, the patient was still having intermittent spasms, but the swallowing reflex had returned and she moved her arm slightly in response to venepuncture The left plantar response was extensor After another two hours there was a withdrawal reflex of the left leg, but this disappeared within an hour Forty one hours after she had taken the glutethimide, an electro encephalogram (E E G) was recorded before, during, and after the injection of bemegride and amiphenazole (see later) Seven hours later the pupils started to react to light and the strabismus disappeared After a further two hours she began to talk, and then became restless and required 4 ml paraldehyde for sedation

Next morning there were no abnormal signs at all apart from rapid nystagmus to either side This disappeared in twenty four hours She was very depressed and had to be transferred to a mental hospital

The Electro encephalogram

Forty one hours after taking glutethimide (patient still in coma) —The most persistent component was symmetrical 5 to 6 c per sec activity which was fairly generalised, though of slightly higher amplitude (about 40 µV mean), in the frontal regions Frequent runs of delta activity were seen here with a peak amplitude of up to 150 µV, but at no time were these truly paroxysmal No faster components were seen The intravenous injection of 100 mg bemegride preceded by 30 mg of amiphenazole produced a short term diminution of amplitude of the slow activity and this coincided with a partial return of her withdrawal reflexes The record returned to its former state thirty seconds after the end of the injection A further 100 mg bemegride and 30 mg amiphenazole had a similar transient effect on the E E G

Eighty four hours after taking glutethimide (patient clinically recovered) —The E E G findings had changed dramatically and were substantially within the limits of normal variation for an alert subject Runs of slow activity appeared during the latter stages of the recording, but were almost certainly due to drowsiness

Electrolytes

There was a slight acidosis soon after admission, probably due to the aspirin, but by the following day the alkali reserve had returned to normal The serum-potassium was low (12 5 mg per 100 ml , 3 2 m eq per litre) but this had returned to normal after ten days

A full blood count and liver function tests were normal two weeks later

Discussion

This patient was admitted in deep coma fourteen hours after taking 40 tablets of glutethimide (10 g) and 16 aspirin tablets (4 8 g) Despite the large dose of glutethimide, respiration was not grossly depressed This may be partly attributed to the stimulation of respiration by aspirin (Farber et al 1949), but I believe that glutethimide in this case did not depress respiration to the same extent as an equivalent dose of barbiturate Respiration was regular Gerster et al (1955) reported hyperthermia, electrocardiographic changes, and tachycardia , but in the present case there were no signs of disturbance of temperature regulation of the cardiovascular system, of the blood picture, or of liver function

An interesting feature was the *tetanic spasm* of the limbs, lasting several minutes, together with laryngeal spasm

Gerster et al (1955) observed that all intratracheal interference had a bad effect on respiration, but in our patient intubation was not attempted and laryngeal spasm was apparently spontaneous Between spasms the patient remained flaccid, and Trousseau's and Chvostek's signs were negative The serum calcium was normal, there was a mild acidosis, and the spasms were not relieved by intravenous calcium gluconate

The spasms were present before treatment, and persisted for twelve hours after the administration of bemegride and amiphenazole , they are presumed to be due to glutethimide Their frequency was increased by bemegride given alone or in combination with amiphenazole but not by amiphenazole alone

Bemegride and amiphenazole were given by the method of Shulman et al (1955) The knee jerks returned in one and three quarter hours, by which time 750 mg bemegride and 225 mg amiphenazole had been given The corneal and pupillary reflexes were the last ones to reappear, twenty-six hours later—about four hours before the patient regained consciousness A total of 1350 mg bemegride and 570 mg amiphenazole was given

The observations suggest that in glutethimide poisoning bemegride and amiphenazole stimulate reflex activity as well as respiration Amiphenazole in particular, increases the depth rather than the rate of respiration The alteration in the electro encephalogram is only transient if the drugs are used intermittently, and it is probably preferable to treat cases by continuous infusion as described by Clemmesen (1956) The only metabolic disturbance noticed was a decrease in the serum potassium, which has been recorded in the treatment of barbiturate poisoning with bemegride and amiphenazole (Shulman et al 1955) No mental disturbances were observed which could be ascribed to the treatment

Summary

A case of poisoning with 10 g glutethimide (' Doriden ') and 4 8 g aspirin is reported Frequent short lived attacks of laryngeal and tetanic limb spasm were thought to be due to glutethimide

Treatment with bemegride (' Megimide ') and amiphenazole (' Daptazole ') resulted in the return of reflex activity, increased respiration, and caused transient alteration in the electro encephalogram

These drugs are recommended in the treatment of poisoning by glutethimide

I am grateful to Dr C N Armstrong for permission to publish this case   I should also like to thank Dr B McStay and Dr J Wilson for their help in the treatment, and Mr J. W Osselton for reporting on the electro encephalograms

ACUTE PANCREATITIS IN A CHILD AGED 3 YEARS

B W T PENDER
M B Lond, F R C S
SENIOR SURGICAL REGISTRAR, ST GEORGE'S HOSPITAL, LONDON

IT has long been recognised that acute pancreatitis may occur in children, although it is extremely rare except in association with mumps

Farnham (1922) collected 119 cases of mumps pancreatitis, of which 117 recovered   Dey (1951) reported a case of acute hæmorrhagic pancreatitis in a child aged 22 months, on laparotomy he found bloodstained fluid in the peritoneal cavity, widespread fat necrosis, and a hard swollen pancreas   No serological investigation was made, but the patient's sister was admitted to another hospital with mumps at the same time

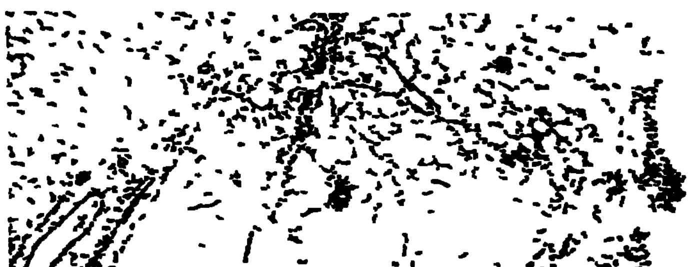
About 18 cases have been reported in children under the age of 13, who, so far as could be ascertained without serological tests, were free from mumps   Dobbs (1935) added 1 of his own to 14 collected cases aged 2–13

I report here a case in a child, aged 3 years, apparently without mumps

Case-report

A girl born on Sept 19, 1950, was admitted to the Victoria Hospital for Children, Tite Street, London, on April 5, 1954

History—Four days before admission she vomited several times and complained of abdominal pain   Three days before admission she developed a cough, and on the day of admission her abdominal pain became very severe and colicky, and she was completely constipated   Her mother stated that she had had a similar illness two years previously



Fat necrosis of greater omentum   (Hæmatoxylin and eosin ×45)

She was the third of five children   There had been no recent illness at home, nor was she known to have been in contact with any infectious disease

Examination—She was a flushed well developed child with a cough, temperature 99 4°F, pulse rate 100, and respirations 28 a minute, weight 33 lb 6 oz   She had enlarged injected tonsils and cervical adenitis   She was extremely tender round the umbilicus and there was general abdominal guarding There was no rigidity, and no mass was felt in her abdomen Her rectum was empty, but on bimanual examination fæces were felt in the colon above   No other abnormality was found

Tonsillitis with mesenteric adenitis was diagnosed

Progress—Next day her abdominal signs were less generalised, the tenderness being greater in the right hypochondrium No abnormality was found in her urine   A throat swab grew scanty β-hæmolytic streptococci   Her hæmoglobin was 70% A white-cell count showed 8100 cells per c.mm   A chest radiograph was clear

Next morning (April 7) her pulse rate rose and she looked pale, shocked, and ill and had fairly severe attacks of pain The tenderness was still worst in the right hypochondrium, and the right rectus muscle was now in spasm   In view of the change in the clinical picture it was thought that the child might have an acutely inflamed high appendix or even cholecystitis   Laparotomy was therefore advised

Operation (April 7)—A right mid-paramedian incision was made under general anæsthesia   There was no free fluid in the abdomen, but widespread fat necrosis was seen on the parietal peritoneum and greater and lesser omenta   The lesser sac was opened, and the pancreas was found to be hard, enlarged, and œdematous, its surface being covered with widespread fat necrosis, mostly appearing as white specks as big as a large pin head and making the surface of the pancreas feel like emery paper   The parietal fat necroses were very much larger, and one was removed from the greater omentum for microscopy   The gall bladder was extremely tense but was emptied by pressure and was without doubt the cause of the local tenderness   No stones were palpable in the biliary tract

Postoperatively, on April 8, the patient's serum amylase level was 160 units per 100 ml   Biopsy confirmed the diagnosis of fat necrosis (see figure)   A mumps complement fixation test showed no antibodies to the mumps virus at a titre of 1   5 in serum collected on the 4th and 5th days of the illness The patient convalesced uneventfully and has since remained well

Discussion

In view of the serological tests it can be stated with certainty that the cause was not mumps   The tenderness localised to the right hypochondrium on the second day in hospital was due to the tense gall-bladder   At no time was there any cyanosis or jaundice, and it is doubtful whether the diagnosis could have been suspected preoperatively   The child had had a similar attack, which settled, two years previously

In Dey's (1951) case there had been no previous history, the white cell count was 24,000 per c mm, and bloodstained fluid and fat necrosis were found on laparotomy   The pancreas was hard and swollen, but the biliary system was normal

Steiner and Tracy (1943) found an association between pancreatitis and diabetic coma in 10 children examined post mortem   They also cited 4 other cases of pancreatitis found among 26 children who died in diabetic coma   There was no association with diabetes in either the present case or Dey's (1951) case

In the 14 cases collected by Dobbs (1935) no cause was found in 6, an impacted gall stone was responsible in 1, there had been trauma in 3 (a cart running over the abdomen in 2), roundworms were certainly responsible in 1 case (a Hindu girl, aged 12 years had two round-worms removed from the pancreatic duct through an incision in the pancreas) and probably responsible in 2 cases, and 1 case was probably due to a septic embolus in the pancreas

Summary

A case of acute pancreatitis in a child aged 3 years is described. Serological tests excluded mumps

Biopsy showed fat necrosis

The child convalesced satisfactorily and has been symptom free for more than two years

I wish to thank Dr C Pinckney for asking me to see and operate on his patient and for allowing me to publish the case, Prof T Crawford for his photomicrograph, and Dr A Dudgeon for the comprehensive serological tests

Medical Societies

MANCHESTER MEDICAL SOCIETY

Social Pathology of Coronary-artery Disease

ON Jan 23 Dr J N MORRIS (London), in an address to the sections of medicine and pathology, suggested that coronary atheroma was rife before the first world war but ischæmic heart disease was less common than now A national survey of necropsies on middle aged men had shown an excess of ischæmic myocardial fibrosis in "light" workers dying of cancer, injuries, &c This excess was particularly evident among patients with solitary scars of large healed infarcts—an observation which might give a link with the previously recorded excess of "sudden deaths" and other rapidly fatal ischæmic heart-disease in sedentary workers, such as bus-drivers and clerks

What might be called the "appeal to epidemiology" was persistently refusing to confirm hypotheses of a single or simple dietary ætiology for ischæmic heart disease In the present climate of opinion such a negative rôle was exceedingly uncomfortable ! But it was not possible, in time series or other series, to correlate what was known of the mortality from coronary heart disease with what was known of trends in fat consumption Thus, the great variations of mortality among Western countries having similar high fat intake disposed of any story that total fat consumption was the critical factor Changes in animal-fat consumption in the United Kingdom during the present century could be related to the changes in coronary atheroma found in the London Hospital records, but they showed no relation to the Registrar General's figures of mortality from coronary heart disease The trend of consumption of butter-fat in the United Kingdom showed absolutely *no relation*, the steep increase in coronary deaths since 1943 was only one illustration of this Changes in vegetable-fat intake followed the mortality experience more *closely*, and changes in hydrogenated fat intake were even more closely reflected in the mortality figures, except for the social-class distribution of coronary mortality, which did not agree with the pattern of margarine intake International experience was even more contradictory Norwegians, who ate a lot of margarine, seemed to have far less fatal "coronary thrombosis" than New Zealanders, who ate very little Perhaps the fish the Norwegians ate protected them, but this did not seem to help Aberdeen, which registered twice the coronary death rate of Oslo

In terms of the total of essential fatty acids themselves, the only available data for the United Kingdom gave no support to the hypothesis that the population was now suffering from an absolute or relative deficiency of essential fatty acids, and international comparison again showed anything but a homogeneous picture More and better statistics of disease and of food trends were urgently needed, and it was hopeful that the World Health Organisation had now entered this field

Reviews of Books

Handbook on Poliomyelitis

JOSEPH TRUETA, M D, D SC, F R C S, Nuffield professor of orthopædic surgery, University of Oxford, A B KINNIER WILSON, M B, M R C P, D P M, member of the scientific staff, Medical Research Council, MARGARET AGERHOLM, B M, assistant, Nuffield department of orthopædic surgery, Nuffield Orthopædic Centre, Oxford. *Oxford Blackwell Scientific Publications* 1956 Pp 139 20s

THIS is a compact and pleasantly readable book containing a wealth of up-to-date information

The first section includes history, virus studies, epidemiology, pathology, clinical manifestations, and diagnosis, and there are valuable sections on treatment in the acute stage and on specific preventive measures Nearly a quarter of the text is taken up by chapters dealing with the diagnosis and management of cases with complications affecting the respiratory muscles The final chapters deal with the treatment of cases during the transitional, recovery, and chronic periods The authors have avoided the temptation to present every aspect of complex surgical procedures, and instead have set out the arguments for particular forms of management and treatment in a way that is satisfying without being provocative

The book will be read with pleasure even by those with only slight knowledge of the subject, and to the expert it will rarely fail to supply in concise form such information as he seeks

Outline of Fractures

Including Joint Injuries JOHN CRAWFORD ADAMS, M.D., F R C S, *consultant orthopædic surgeon,* St Mary's Hospital, London Edinburgh and London E & S Livingstone 1957 Pp 248 27s 6d

THIS is the companion volume to the author's Outline of Orthopædics, published last year, and like this earlier book it is intended for the medical student and the general practitioner Mr Adams has an incisive mind and a lucid style, which will make this a popular book for the student

Possibly the insistence on brevity has sometimes been carried almost too far, so that the student may have to turn to larger textbooks for clarification for instance, the section on the circulation in an injured limb might well be expanded Future editions—which will surely be *demanded*—might include some further advice on handling a fractured limb at the first aid stage, in the chapter on general features of fractures a summary of the differences to be found in children might be included, and the illustration showing the never effective spring clips holding the bands on the Thomas splint should be changed

This generally excellent book can be warmly recommended to the medical student

Clinical Examinations in Neurology

By members of the Sections of Neurology and Section of Physiology, Mayo Clinic and Mayo Foundation for Medical Education and Research, Rochester, Minnesota. Philadelphia and London W B Saunders 1956 Pp 370 52s 6d

THIS book contains a useful account of methods of clinical examination in neurology and of the interpretation of physical signs There is a brief account of electro-encephalography, of the electrical testing of muscle, and of the methods of obtaining cerebrospinal fluid but neuro-radiology is not dealt with The book follows conventional lines, but it is clearly written and provides a valuable introduction to neurological case taking

---

Modern Treatment Yearbook (London Baillière, Tindall, & Cox 1957 Pp 312 25s)—As Sir Cecil Wakeley, its editor observes in a preface, the yearbook's aim is to present the general practitioner with the advice of experts on up to date treatment Those who are familiar with it will know how seldom it misses the mark Among the contributors to the new volume, Dr P M I Bishop acts as a Young Person's Guide to the Endocrine Orchestra and Dr J B Harman writes helpfully on the treatment of incurable malignant disease

THE LANCET

LONDON SATURDAY, FEB 23, 1957

Industrial Lung Cancer

The study of industrial pulmonary cancer has special significance at present, when much effort is being expended in many countries to determine whether environmental factors, such as atmospheric pollution or tobacco-smoking or both, are the essential causes of the world-wide increase in lung cancer. Every well-conducted study of an industrial hazard yields some information about the nature of the exposure or the response of the tissues to that exposure, and in six industries the hazard of lung cancer is well proved; in many others there is suspicion but no proof.

The story of the Schneeberg and Joachimstal miners' cancer is an old one, and it was this disease which firmly established the association between industrial exposure and pulmonary cancer. Today we have no further reliable information about the real cause than we had when the condition was first described in 1879. The ore concerned, pitchblende, has a uranium content of about 70%, but it also contains small quantities of oxides of rare earth metals, together with thorium, lead, zinc, manganese, silica, iron, cobalt, and nickel. The high uranium content suggests that radioactivity is at least partly responsible for the induction of the tumours, but there is no proof of this, and attempts to demonstrate radioactivity in affected lungs have failed.[1] There is also much uncertainty as to whether fibrosis does or does not precede the cancer. Another group exposed to danger are gas-retort workers. KENNAWAY and KENNAWAY[2] showed that they were about three times more liable to cancer of the lung than the general male population during the years 1921–38. The number of people employed in this way was not great, but the association seemed to be a real one. DOLL[3] found that recorded deaths from lung cancer in gas-works pensioners were nearly twice as many as would be expected from a comparison with the general run of men in London. The excess mortality lay principally among employees engaged in the production of gas and the treatment of waste products—i.e., among men actually working in the retort houses.

A third type of industrial lung cancer that has long been recognised in Germany is that found among those working on the production of chromates. In recent years the same liability has become apparent in the United States; and BIDSTRUP and CASE[4] have lately drawn attention to a similar hazard in Great Britain. They surveyed the causes of death among the employees in three factories in different parts of the country, and they found that deaths from cancer of the lung were between three and four times more numerous than they were among the general male population of England and Wales of the same age-groups. The deaths of 12 chromate workers were ascribed to lung cancer: the diagnosis was confirmed by necropsy in 4 cases and by biopsy in 3 more; in 5 others it was made on clinical and radiological findings. The industrial process involves extraction of chromium from the ferrous ore known as chromite or chrome iron-stone, which contains 30% or more of chrome oxide, and 15% of ferric and silicon oxides. The pneumoconiosis due to inhalation of insoluble chromium compounds (or chromitosis) is said to consist of a spotty fibrous thickening of the peribronchial and interstitial tissue, where the chromium dust particles are deposited.[5] In exposed workers, the chromium content of affected lungs is higher than that of other organs.[5,6] It is interesting to note that although perforation of the nasal septum and skin ulceration are well-known signs of over-exposure to chromate compounds, malignant tumours have not been described in the nose or skin of chromate workers.

Asbestos and nickel are two other substances associated with an increase in lung cancer. Workers in the asbestos textile industry suffered in former years from a severe form of pulmonary fibrosis, now known to be related to the subsequent development of lung cancer[7,8]; and similar findings have been reported from Germany, Canada, and the United States. Some ores contain ferrous and silicon oxides in high proportion; other ores, notably that found in Canada, contain only small amounts of iron oxide. The short fibres of the Canadian ore are said to be more dangerous than the long fibres of some other ores.[9] In this form of industrial cancer, there is no doubt that fibrosis precedes the malignant process; and it is also clear that the exposed female is susceptible to the disease. Cancers of the nasal passages and lung have been described among nickel-refinery workers in South Wales. Nearly all the tumours arose in workers exposed before 1924, when the plant was reconstructed. The men were exposed to nickel dust and to nickel-carbonyl vapours, but it is not known which was the responsible agent. AMOR[10] stated that refined nickel-copper ores were free from radioactive matter. Pneumoconiosis has not been recorded as a precursor of this type of cancer.

There has been controversy about the part played by iron ores in industrial lung cancer, but the recent work of FAULDS and STEWART[11] goes a long way towards indicting iron-ore mining as a cancer hazard. Ferric oxide is the chief constituent of the hæmatite ore mined in Cumberland, and the ore also contains 10–12% of silica. From 1932 to 1953, 2401 post-mortem examinations were made in Cumberland on men over the age of 30. Of these, 180 were on hæmatite miners and 17 (just under 10%) were found to have carcinoma of the lung; of the remaining 2221 necropsies on men over 30 who had not been hæmatite miners, 45 (2%) revealed cancer of the lung. This four- to five-fold increase among the miners is highly significant. FAULDS and STEWART also pointed to other data which support the view that the cancers were related to the mining In 12 of the 17 cancers, the primary site was regarded as being in the peripheral part of a lobe (either upper or lower) (The densest areas of fibrosis and the tumours were much easier to locate accurately when the lungs were inflated before fixation and full-size sections cut according to the technique of Gough and Wentworth[12]) It, was concluded that "the distribution of primary tumours *in the lungs of hæmatite miners closely follows that* of the areas where sidero-silicotic fibrosis is most pronounced and where it *presumably originated*" But Faulds and Stewart also noted that carcinoma usually arose in lungs which were *not* the seat of the most advanced general fibrosis, suggesting that an optimum or focal fibrosis is more conducive to the development of bronchial cancer Thorough chemical examination of lung tissue removed at death showed that cancerous lungs had the highest silica content, but their iron content was not appreciably greater than normal Finally, a careful search for radioactivity in the ore and in cancerous and non-cancerous hæmatite lungs proved fruitless, so it seems that radioactivity can be excluded as a cause or even a contributory *factor in lung cancer in hæmatite miners*

The way is now open to a more detailed study of the industrial lung cancers that are already known and to a vigilant watch for new chemical hazards Post-mortem examination of the lungs has already yielded much information, but there is scope for more detailed inquiry into the distribution of the tumours, their relation to pre existing fibrosis, and their histological character, and these aspects must be coupled with careful chemical analysis and measurements of radioactivity So far no suitable experimental animal has been found Vorwald[13] claimed to have induced squamous carcinomas in the bronchus of the rat by causing the animals to inhale a dust of soluble and insoluble beryllium compounds, and this seems to be the nearest experimental approach to the human disease yet achieved A helpful guide to what is known about industrial lung cancer has lately been provided by Hueper[14]

The Liver in Hæmochromatosis

In classical hæmochromatosis an inborn error of metabolism is thought to be responsible for the extensive deposition of iron, in the form of hæmosiderin, in the viscera and skin, and hepatic cirrhosis and diabetes mellitus are among the consequences The total amount of iron in the body, normally about 4 5 g, is greatly increased and may reach as much as 30 g Since the normal daily intake in the diet is 5–15 mg, complete absorption and retention of the dietary iron for eight to twenty-five years would be *necessary to reach the levels observed in hæmochromatosis*, but it is doubtful whether either absorption or *retention is ever complete*, so that an even longer period of disturbed iron metabolism is probably required

It has long been recognised that a superficially similar picture can follow the administration of very large quantities of iron compounds by mouth or, more especially by injection The hæmosiderosis which results is said to differ in many ways from hæmochromatosis, particularly in the absence of cirrhosis and diabetes and in the more restricted distribution of the iron deposits Much is also known about how repeated blood-transfusions can similarly load the body with iron Sheldon's opinion[1] was that excessive destruction of blood and storage of iron did not produce classical hæmochromatosis but only a simple hæmosiderosis without tissue damage, and there is experimental evidence to justify his view But, as Pengelly and Jones[2] lately remarked, there are now enough published reports of cases of transfusion siderosis with "fibrosis" if not definite cirrhosis of the liver to suggest that hæmosiderin can damage cells—at any rate liver cells Now that blood is available for transfusion in almost unlimited quantities many patients with hypoplastic and hæmolytic anæmias can be kept alive for years (Pengelly and Jones's patient, in whom the full clinical picture of hæmochromatosis developed after nine years of regular transfusions, had a hypoplastic anæmia) The inability of these patients to increase their iron excretion above the normal level of 0 5–1 3 mg daily *leads to the accumulation of iron in quantities which* eventually reach the range found in typical idiopathic hæmochromatosis, so that the hepatic cirrhosis and the diabetes can appear[3 4] On the other hand, a recent appraisal of the situation by Rather[5] suggests that mere overloading with iron may not alone be sufficient to evoke the full picture The crux of the matter is that no one has succeeded in *producing diffuse fibrosis of the liver by simple overloading with* iron compounds In his own experiments Rather studied rats kept on a diet containing either 4% or 16% of protein to which was added 6% of ferric citrate In the control rats on similar diets but without the ferric citrate the iron content of the liver ranged from 32 to 111 mg per 100 g dry weight In the rats receiving the iron supplement the corresponding figures were 720–3180 mg The experiment lasted approximately five hundred days Despite such long and excessive feeding with ferric salts and the accumulation of enormous quantities of iron in the liver, there was *no evidence of hepatic cirrhosis or even of significant liver damage* It seems that, at least in the rat something more than an alimentary overload of iron is needed to produce a condition like classical hæmochromatosis

There is no reason to believe that the patient with idiopathic hæmochromatosis has been exposed to an excess of iron in the diet, and the accumulation in the tissues is presumably the result of increased absorption from a normal diet This increased absorption has been *convincingly demonstrated by* Peterson and Ettinger[6] by giving radioactive iron and estimating the activity of the unabsorbed iron in the stools They found that normal absorption was between 1% and 4% of the intake, whereas in 2 patients with hæmochromatosis it was 20% and 40% respectively The way in which the absorption of iron from the gut is controlled is still obscure The apoferritin-ferritin system of control described by

Granick[7] can certainly be overcome by giving large quantities of iron, but, even when the intake of iron is relatively small, absorption can be strikingly increased by appropriate changes in the diet. By substituting a diet of corn grit and 20% lard for one of Purina dog chow, Kinney et al[8] were able to produce considerable hepatic siderosis in rats who had 2% ferric citrate added to their food. The effective diet in this experiment was apparently deficient in lipotropic factors and produced not only an increase of iron absorption but significant fatty infiltration of the liver—a condition known to lead to hepatic cirrhosis if it is severe enough. The inference seems to be that something which leads to cirrhosis may simultaneously interfere with the normal intestinal mechanism for the control of iron absorption. The incidence of hepatic siderosis in malnourished Africans[9] supports this conclusion, but the absence of any sign of nutritional deficiency in the Australian survey by Althausen et al[10] suggests that the fault in intestinal control may be initiated in other ways. The enhanced absorption of iron by cats in which the pancreatic duct has been ligated was first reported by Taylor,[11] and the observation was confirmed in dogs.[8] This finding suggests that the involvement of the pancreas in hæmochromatosis, if not a primary fault, may well promote a vicious circle.

It is not yet clear how much iron the liver cells can stand. Sudden large doses of iron salts have been shown experimentally to cause acute liver damage,[12] and children dying of ferrous-sulphate poisoning may have conspicuous toxic changes in their livers. But slowly mounting quantities of iron can be tolerated for a long time by an otherwise normal liver, and the present weight of evidence is against the view that the iron deposits are alone responsible for the hepatic damage in hæmochromatosis.

The Adrenal Cortex in Hypertension

Some relation between the blood-pressure and the adrenal glands had been recognised for about a hundred years when Addison first described the feeble pulse in the disease which now bears his name and in which both adrenal glands are destroyed by caseous necrosis or atrophy. Later the sphygmomanometer amply confirmed the low blood-pressure in Addison's disease. In 1895 Oliver and Schafer[13] demonstrated the remarkable rise in blood-pressure which followed an injection of an extract of adrenal medulla and when, some years later, Abel[14] isolated a crystalline "epinephrine," it was generally believed that this substance was responsible for the maintenance of normal blood-pressure and also for hypertensive states. It has been shown beyond doubt, however, that Addison's disease is due to the destruction of the adrenal cortex and that normal blood-pressure can be restored by cortical extracts. In recent years some have advocated a hypothesis which considers the action of adrenaline as synergistic to that of the corticoids,[15] and the adrenal gland as a single functional unit. This view is the *Leitmotiv* of Chwalla's book[16] on hyperfunction of the adrenal, but the evidence to support this attractive hypothesis is meagre, and other workers in this field prefer to concentrate their attention on the adrenal cortex and its hormones. Goldblatt[17] found (and it has since been confirmed) that the hypertension which follows constriction of the renal arteries can be reduced to normal levels by bilateral adrenalectomy. This effect of adrenalectomy has been attributed to the elimination of cortical hormones.[18–20] The mineralocorticoids are the hormones which raise the blood-pressure, and deoxycortone is the one which has been most closely studied. These hormones are apparently responsible for the hypertension produced by many neoplasms of the adrenal cortex, particularly those associated with a Cushing syndrome. Further important observations are that hypertension, with its pathological effects, can readily be produced by deoxycortone in Addison's disease and in adrenalectomised animals, but with difficulty or not at all in the presence of normal adrenals. Moreover, hypertension was produced by deoxycortone but not by crude extract of total adrenal cortex.[21] From these findings, Soffer[22] concluded that the adrenal cortex produced an additional blood-pressure-balancing fraction, as well as the hypertensive factor.

Understandably, these developments have directed attention to the morbid anatomy of the adrenal glands in essential and in renal hypertension, and a thorough investigation of this subject has lately been recorded by Dawson.[23] He has studied 90 adrenals from people with normal blood-pressure, 90 from patients with essential hypertension, and 44 from others with renal hypertension. The investigation included weighing the organs, measuring the thickness of the capsule and each of the three zones of the cortex, and staining by routine methods and those designed to display fats. Dawson also used digitonin precipitation, the polarising microscope, and the Ashbel-Seligman method, which is believed to demonstrate ketone groups. The average combined weight of the glands was 15·3 g in essential hypertension and 15·7 g in renal hypertension, compared with 11·8 g in the normotensive group. The enlargement was due to hyperplasia of the zona fasciculata, associated with an irregular arrangement of the cells, which were hypertrophied and vacuolated and contained abundant lipid. The changes in renal hypertension differed from those in essential hypertension mainly in the greater extent of the zona reticularis; the difference seemed to be quantitative rather than qualitative. The zona glomerulosa was not affected in either form of hypertension. Signs of exhaustion of the cortex were seen in renal but not in essential hypertension. It may be, however, that the presence or absence of lipids is not conclusive evidence of activity or exhaustion,[24] and to get a more accurate picture fat stains may have to be combined with histochemical demonstration and quantitative estimation of the dehydrogenase activity, using the tetrazolium-salt method, which gives reliable results with post-mortem material

DAWSON believes that the changes in the adrenal cortex in hypertension are secondary, "since it is difficult to conceive of a primary adrenal change in renal hypertension" This reasonable assumption seems more likely to be true than that of CHWALLA,[16] who holds that the hyperplasia of cortex and medulla comes first, and predisposes to a variety of diseases, among them hypertension Even if the cortical changes can reasonably be taken as secondary effects, there is little to point to their significance Are they evidence of an increased formation of blood-pressure-raising hormones to counteract the effect of the primary disease and thus improve the blood-flow, or do they indicate compensatory formation of a hormone that depresses the blood-pressure[2] Such a hormone has not yet been isolated but its existence was suggested by SOFFER[22] because of the different actions on the blood-pressure of deoxycortone on the one hand and total cortical extracts on the other It is unlikely that the changes in the cortex indicate a cortical control of the secretion of medullary hormones, because hypertensive individuals excrete in the urine adrenaline in similar amounts to normal people[25]

A FLYING-SQUAD COMES OF AGE

THIS week the 21st anniversary of the Newcastle Obstetric Emergency Service was being marked by celebrations which included the presentation of a portrait to Emeritus Professor E Farquhar Murray, who took a leading part in its inception This flying squad service was brought into being mainly to save lives that might be lost during the journey from home to hospital—notably through the third stage complications of hæmorrhage, retained placenta, and shock There are now flying-squads based on over a hundred and seventy maternity hospitals or units in England and Wales, and third stage complications account for three quarters of the calls, which amount in all to about 1% of domiciliary deliveries Complications are often unpredictable, but experience has shown that, because of the enhanced risk, patients who have previously had third stage complications, pregnant women who are expecting twins, and grand-multiparæ should not be booked for home confinement

From a modest 11 cases in 1936 (the first full year of operation), the number of cases dealt with by the Newcastle service grew to a record total of 146 in 1955 The Newcastle scheme, directed since 1950 by Prof Harvey Evers, has been the prototype for many elsewhere —but not for all, since the best form depends on local geographical and other factors In Newcastle each call is answered by an experienced obstetrician, and nowadays he is accompanied by an anæsthetist, whose help has proved invaluable A senior sister from the antenatal department of the Princess Mary Maternity Hospital (on which the service is based) also attends The flying-squad is comprehensively equipped, and the patient is rarely moved to hospital Calls come from up to sixty miles away, and for this large area a policy of simple resuscitation and rapid transfer to hospital by ambulance (which has been adopted by some other flying squads) has never been applied

Improved antenatal care and selection of cases for delivery in hospital would somewhat reduce, but could not abolish, the calls on obstetric flying-squads The service started in 1935 by Professor Farquhar Murray and his associates is now recognised as a permanent and indispensable feature

CHLOROQUINE IN RHEUMATOID ARTHRITIS

THE discovery that antimalarial drugs may be beneficial in rheumatoid arthritis stems from one chance observation and two theoretical ideas Reporting that mepacrine was helpful in lupus erythematosus, Page[1] mentioned a patient in whom a polyarthritis of rheumatoid type improved at the same time as the skin lesion. Lupus erythematosus, especially the systemic type, is certainly outstanding among the diffuse mesenchymal diseases in the closeness with which any associated arthropathy may resemble rheumatoid arthritis Hence it was natural that mepacrine, although more clearly effective in the discoid than the systemic form of lupus erythematosus, should be tried in rheumatoid arthritis.[1] Haydu,[3] in the belief that the tissue requirements for adenosine triphosphate are increased in rheumatoid arthritis, tried chloroquine because, like other methods known to be effective, it inhibits adenosine triphosphatase That adenosine triphosphate is involved in this way in the pathogenesis of rheumatoid arthritis is at present no more than a suggestion based on certain hypothetical considerations Freedman,[4] who has lately recorded his experience with chloroquine in rheumatoid arthritis, is attracted by the view that rheumatoid arthritis is an infective condition, and that antimalarial drugs may have a chemotherapeutic action

The rationale of treatment with chloroquine is thus insecure, but Freedman's claim to have demonstrated its efficacy is based, unlike that of other investigators,[3 5 6] on a properly controlled clinical trial, and must be carefully examined The trial included 66 patients, and in most of them the effect of treatment was measured throughout a period of sixteen weeks Patients were allocated at random to the experimental and control groups All received a regular dose of aspirin and ascorbic acid The experimental group were given 200–300 mg daily of chloroquine, and the control group an equivalent number of dummy tablets Assessments of response were made without knowledge of the type of treatment The chloroquine patients improved to a degree which was *statistically significant* as far as tenderness of joints, strength of grip, and dexterity were concerned, but there was no definite change in the time taken to walk a measured distance, in the hæmoglobin level, or in the erythrocyte-sedimentation rate As Freedman himself points out, the improvement in the chloroquine group was modest Clinically there was (as would be expected) some improvement in both groups, but statistical analysis showed that only the change in the chloroquine group was significant It is not clear whether the difference between the degree of improvement in the two groups reached significance The two groups were not evenly matched, since the chloroquine group contained rather more patients with disease of recent onset and with slightly more active disease As Duthie et al[7] have shown, this would tend to weight the outcome in favour of chloroquine treatment Freedman held that this factor could not account for the difference between the treated and control group, but he does not give figures

Sixteen weeks is a short sample of the natural history of rheumatoid arthritis Any drug which influences the disease even briefly is of great interest, but only a longer trial can establish or refute the practical value of any treatment Freedman did, in fact, treat a group of patients for a longer period This part of his investigation was, however, uncontrolled, and serves mainly to establish the superiority of chloroquine over mepacrine in terms of toxic effects Freedman wisely concluded that the trial did not definitely prove the value of prolonged treatment with chloroquine in rheumatoid arthritis, but he believed that his data warranted a larger investigation

HELP IN THE HOME

TODAY any report worthy of the name—whether about old people or babies, hospitals or clinics, general practitioners or consultants, the family or the isolate, tuberculosis or mental disease—is likely to recommend "the development of the domiciliary services" In a world of almost frightening scientific progress and mechanical complexity, it is perhaps rather consoling that the answer to many urgent medical problems should be the simple words "more help in the home" But their simplicity is deceptive, and some of the difficulties, achievements, and resources which they cover will be found by the attentive reader of the recent report on London's health [1]

The three principal services which offer help in the home are the home nurses, the home helps, and the health visitors In London the home nurses are provided by 27 voluntary associations acting as agents for the London County Council through the Central Council for District Nursing in London At the end of 1955, 572 whole- or part time nurses were available, of whom 49 were men This force paid nearly 2 million visits, giving an average of 13 visits daily and a case load of 24 for each nurse 41% of the patients were over sixty-five years of age and 6% were children under five Besides providing the associations with a grant of 93% of their expenses, the L C C lent them 21 cars, and at the beginning of 1955 it appointed a supervisor who has during the year visited all the associations and where necessary advised in day-to day problems Through the British Red Cross Society the L C C also lends nursing equipment for patients who are getting care in their homes The demand for expensive and unusual equipment is growing because many chronic sick and disabled who were formerly held to be hospital cases are now able to live at home For example, as a result of the work of the National Spinal Injuries Unit at Stoke Mandeville Hospital, many more paraplegics are now able to look after themselves

The home help service is also growing steadily if slowly At the end of 1955, there were 3148 helps—the equivalent of 2029 full-timers—compared with 2996 and 1866 respectively in 1953 Over 80% of their work in 1955 was for the aged and chronic sick This service is short of staff, but, thanks to the policy of giving some assistance to all in need, only 61 applications had to be deferred or refused in 1955 compared with 161 in 1954 Night helps sit with patients in their homes to allow relatives to get some sleep but, surprisingly, the demand on this useful aid is not heavy, and in 1955 the 48 new applications were met

The scheme, started as an experiment, to provide help in a family crisis so that the children need not be received into care is being extended and is now offered for families with only one child (Previously it was limited to families with at least two children) The demand on this service is not yet as heavy as was expected—5 families (16 children) in 1955—but early morning and evening help, arranged to cover the gaps between school hours and parents' working hours, was supplied for 205 new families in 1955 compared to 85 in 1954 At the end of the year a scheme was being started to prepare selected home helps to work with the health visitors and teach the rudiments of housecraft to inexperienced mothers in homes which are in danger of breaking down The success of this preventive work is most clearly shown in the detailed reports from the boroughs, which record that in two L C C divisions it was possible to avoid taking 75 and 135 children into care

These divisional reports also show how much the 375 health visitors are contributing and how their work is widening In many London boroughs there are monthly reviews of problem families and potential problem families who with a little timely help can make a reasonably speedy return to normal One division also records that the health visitors are finding it possible to give more time to the lonely ailing old people Informal meetings are being held with the local family doctors at health and welfare centres Another successful experiment was to attach a health visitor for part of her time to a group practice Valuable domiciliary work is being done by health visitors in connection with the diabetic unit at King's College Hospital, and several health visitors have started classes in antenatal relaxation and exercise

These extra pairs of skilled hands, offering timely aid in a home for even a few hours a day, have freed many hospital beds and spared many families from anxiety, exhaustion, and separation

LARYNGEAL GRANULOMA AFTER INTUBATION

A GRANULOMA involving one or both vocal cords is a rare complication of endotracheal anæsthesia In recent years it has been gaining recognition as a clinical entity and this increase reflects the wider use of intubation in modern surgery Discussing these granulomas, Epstein and Winston [1] record 10 cases treated at the Royal National Throat, Nose and Ear Hospital in London All the patients were adults, and women outnumbered men by 4 to 1 The relatively small laryngeal aperture in the female may make women more susceptible Direct injury to the larynx during the introduction of the tube seems to play only a small part, since most granulomas followed an easy intubation, often performed with the aid of muscular relaxants Pressure of the tube in the glottis is probably the most important cause, and this view is supported by the fact that the granulomas always arise on the vocal process of the arytenoid and by the demonstration [2] of the spring-like action of the flexible endotracheal tube, which exerts pressure posteriorly in the larynx, increasingly so as the head is flexed The rigid bronchoscope, on the other hand, lies against the anterior commissure, and a granuloma has never been recorded as a sequel to bronchoscopy

The vocal process of the arytenoid forms a rigid unit, the mucoperichondrium is firmly adherent to the cartilage it covers and there is no subepithelial connective tissue layer to allow the epithelium to move on underlying structures Injury in this region leads to ulceration and the formation of non specific granulat on tissue Constant trauma from the opposite vocal process causes the granulation tissue to proliferate, and it becomes epithelialised and presents as a sessile granuloma Healing takes place by fibrosis, which narrows the base until the granuloma becomes pedunculated This process may continue until the granuloma is shed and expelled Usually it remains, causing irritation, hoarseness, and sometimes stridor

When an ulcer is seen on the vocal process after an operation involving intubation, the development of a granuloma may sometimes be prevented by insisting on strict voice rest At a later stage, the removal of a sessile granuloma exposes a large bare area which gradually heals by granulation, so that the granuloma may recur Provided the airway is adequate, removal should, therefore, be deferred until the granuloma is pedunculated, and it should be followed by absolute vocal rest

NEW POPULATIONS, OLD PATTERNS

SIX family doctors have surveyed their practice in a new housing estate 15 miles from the centre of London [1] It is the first time that such a community has been the subject of a survey of this kind, by practitioners aware of the possible influence of the new surroundings on the people who have come to live in them

Information was recorded on a modification of the N H S medical-record envelope continuation sheet, then coded, transferred to punch cards, and sorted mechanically A random 25% sample was taken, including 4800 people living in 1018 houses in the area The consultation-rates and numbers of patients consulting were classified by social group as well as by sex and age The results of previous work were confirmed The presence on the estate of families rehoused on grounds of ill health did not apparently raise the consultation rate, perhaps because the low average age of the community cancelled out any such tendency The extent of the "hard core" of the practice is interesting 16% of the registered patients accounted for half the consultations, and the 7% who took up 30% of the consultations represented the real bedrock This aspect of the practice is to be further examined, and an analysis of the causes of these consultations would be of particular interest

It is surprising to learn that as many as 99 prescriptions were issued for every 100 consultations Only about 5% of the registered population consulted the doctor *without* obtaining a prescription—and most of these consultations were for reasons other than sickness The prescription-rate seems high, and analysis of the prescriptions issued, by an arbitrary estimate of their value, might be a useful means of future study

More inquiries of this kind are needed, and we hope for further news from this particular community

VITAMIN-D POISONING

VITAMIN D is often prescribed or taken in large doses, despite the known dangers, for conditions such as arthritis and skin tuberculosis for which more effective and safer treatment is now available Scharfman and Propp [2] have lately described 4 patients with vitamin-D intoxication in which a normochromic and normocytic anæmia was a presenting feature They concluded that this anæmia was probably secondary to the azotæmia which in turn depended on renal impairment caused by the hypercalcæmia of vitamin D poisoning, which may often be unsuspected Debré and Brissaud [3] mentioned anæmia as one of the features in their series of 27 children who had been poisoned by vitamin D

Another suggestion,[4] based on animal experiments, is that excess of vitamin D and cholesterol may be related to the development of atherosclerosis It would be virtually impossible to substantiate this work in man, but it may provide a link with Sinclair's thesis [5] that many modern dietaries are deficient in the essential polyethenoid fatty acids (E F A) and that cholesterol consequently becomes esterified with abnormal or unusually saturated fatty acids which the body finds difficult to dispose of and which could cause atheroma Sinclair has taken his argument a step further [6] by attributing a part in the ætiology of infantile hypercalcæmia to E F A deficiency Sensitivity to vitamin D has been suggested as a cause of infantile hypercalcæmia Sinclair has pointed out that roller dried milk, such as National dried, is relatively low in E F A and rich in vitamin D and that this combination might enhance the action of unesterified vitamin D and thus lead to hypercalcæmia Such a consequence might be regarded as a physiological penalty for our persistence in feeding babies with milk designed for the young of another species, and to which too much vitamin D has been added

Infantile hypercalcæmia is virtually unknown in the United States, where babies are more often fed on evaporated milk or on modified dried milk formulæ, which are richer in E F A and contain less vitamin D But lack of E F A cannot be the only factor since millions of babies are fed on National dried milk and only a few get hypercalcæmia, something else seems necessary to initiate the hypercalcæmia Infection [8] and adrenocortical dysfunction [9] have been suggested as possibilities

These new findings are a reminder that vitamin D is not without its dangers and that there is nothing to be gained by giving amounts vastly in excess of physiological needs [10] Ideal growth and the prevention of rickets in infants can probably be achieved by a daily dose of about 500 international units, and if the vitamin is to be prescribed for older children and adults a similar dose should suffice and should not, as far as we know at present, do any harm

TIRED YOUNG NURSES

IN the autumn of 1954 correspondents in the *Nursing Mirror* discussed whether young nurses are overtaxed and overstrained A few months later, as a result of these letters, a committee, representative of all grades of nurses in training-schools, was set up under the chairmanship of Mr H A Goddard, the director of the Nuffield Investigation Team, to consider the problem further In their report, published this week, the committee attribute much of the overstrain and fatigue of these young women (and men) to mental and emotional rather than physical causes They point out that the nurse, unlike other students, is cut off from her ordinary home life and spends her whole time in an "abnormal atmosphere of sickness and in an 'artificial' community"

To lessen this strain they suggest that for the first year the student nurse's training should follow more closely the conventional academic pattern The nurse should enter the hospital without any preliminary training, but she should live in a hostel not run by the hospital authorities, keep college terms, and go home for vacations She should be on duty for regular hours and her first year should be spent in lectures and ward work entirely under supervision "with no responsibility for ward" At first sight this restriction on contact with patients may seem yet another stitch in the nurse's academic gown But the committee's report shows that there may well be a real need to protect the young nurse from some of the rigours of hospital work The committee sent to 5284 nurses in the South West Metropolitan Region a questionnaire dealing with such subjects as their hours of work, ward equipment, catering arrangements The 1965 replies show, for instance, that half of the students in general hospitals work overtime either regularly or often, compared with just over a quarter in mental hospitals In mental deficiency hospitals all students do some overtime and half of them "often or regularly" Slightly over a third of the students have lectures in off duty times These rigours are no doubt due not to harshness but to shortage of staff and the

A Geriatric Hospital Scheme for Rehabilitating the Aged and Relieving their Relatives

J DeLargy
M B Belf, D P M
CONSULTANT PHYSICIAN IN GERIATRICS, LANGTHORNE AND WHIPPS CROSS HOSPITALS, LONDON

Caring for an aged invalid, who can easily become a neurotic tyrant, is a fruitful cause of domestic strain, leading often to breakdown of the relatives' health This has serious social implications which demand more attention than they now receive In the Wolverhampton inquiry, Sheldon[1] suggested short stay hostels and permanent homes as means of lifting the relatives' burden Our experience at Langthorne Hospital, however, suggests that an alternative way of dealing with the situation may be preferable Certainly something must be done, because at present the cost of strengthening the old and weak is far too often a weakening of the young and strong

The extent of strain in the family circle can be assessed only by visiting the home In 1955 I paid 902 such visits, and I found that in 120 (13%) domestic stress was the principal reason why admission to hospital was sought But, whereas the general practitioner thought in terms of permanent accommodation in hospital, many relatives said that they had no wish to shelve their responsibilities and only wanted a rest—especially a night's unbroken sleep Many seemed to be living on phenobarbitone, and quite a few were having treatment from a psychiatrist These were the circumstances which led us to establish in our hospital what is now known as the social rehabilitation unit

The Unit

The section for women contains 24 beds and is decorated and equipped to produce an atmosphere of social well-being and happily lacks the formality of the average hospital ward The dayroom is pleasant and not too spacious, and has a homely air, open coal fires are provided in the ward and dayroom and are a great social amenity The arrangements and the organisation of the staff are intended to encourage self-reliance of every kind There are aids towards participation in work During their stay, patients have the benefit of chiropody and physiotherapy, and visit the daily activities section of the occupational therapy department, where they are encouraged to cook, wash and dry dishes, sweep the floor, and make a bed Similar accommodation is provided for 10 men and like techniques are employed

Admission

There are no direct admissions to the unit A patient is first seen in his own home and his suitability for this special type of environment is assessed If he is considered suitable, we explain to him and to his relatives that permanent accommodation will not be given Instead, he is to spend six weeks in hospital, followed by six weeks at home and then be readmitted for another six weeks Discharge and readmission will continue in this way as long as is necessary At the end of the stay in hospital the relatives are always given the date for readmission This is of great practical importance because the entire household can be reorganised and routines established which add depth to living not only for the patient but more particularly for the relatives

The table shows a list of the disabilities of 100 patients treated on these lines during the past eighteen months

The Patients

30 patients have died—80% of them during the first and second temporary stays This suggests that the death rate conforms to the usual pattern seen in the general wards of a geriatric unit The disabilit encountered are the usual ones in this particular categor In this series the patients with old hemiplegia, osteo-arthritis, or old fractures of the femur were apt to generate much stress A few comments may be of interest

Old hemiplegia—The average duration of the disabilit was three to four years In the early stages of the illness treatment had been active, but the hospital concerned soon l interest and therapy was discontinued The morale of the patients was low because no attempt had been made to he them to live with their disability 80% were chairfast, ma because the sound limb had become weak through disuse Many were aggressive, making the atmosphere in the household intolerable

MAJOR DISABILITY IN 100 AGED INFIRM PERSONS CAUS DOMESTIC STRESS

Disability	70 women (average age 78)		30 men (average a	
	Patients	Deaths	Patients	Deaths
Old hemiplegia	14	6	8	0
Osteo arthritis	23	2	4	1
Parkinson's disease	5	3	4	[illegible]
Old fracture of femur	11	4	2	0
Cardiac illness	12	3	7	[illegible]
Old cerebral thrombosis	5	5	5	2
Total	70	23	30	7

Old fractures of femur—In 8 patients the fracture had been sustained twelve to eighteen months before the domiciliary visit Orthopædic treatment had been excellent and weight bearing had been achieved, but in order to avoid further fall the relatives had persuaded the patients to remain a little longer in bed each day All had disuse atrophy of both limb The mental health of this group was excellent but they were subject to outbursts which caused serious friction, resulting in 3 instances, in the break up of the family

Osteo arthritis—70% of these patients were obese, and enthusiastic attempts to reduce weight had merely resulted in the production of psychosomatic symptoms causing great tension in the home They were reluctant to lose their symptoms, and many of the relatives had suffered great strain.

Results

As stress and strain in the household was the principal reason why admission to hospital had been sought, we felt that a questionnaire to the relatives after the patient's fourth temporary stay in hospital might help u to estimate the value of the scheme Here are a few case

Case 1—Mr A, aged 70, had a useless left arm and hand (an old disability due to poliomyelitis) gross osteo arthritis of hips and knees, flexion contracture of legs, and incontinence of urine He was mildly confused at times, there were aggressive outbursts, and his wife had an acute anxiety state He has been admitted seven times for temporary stay

Reply to questionnaire (by wife)—Arrangement of g help This is the first real rest I have had in two years H attitude to me has improved and he is much easier to man I am very grateful

Case, 2—Mrs B, aged 69, was chairfast because of Parkinson's disease, and was unable to feed herself Bout of urinary incontinence produced emotional crises Husband had given up a very good job to care for her, she demanded constant attention The family doctor asked for permanent hospital accommodation because the situation was intolerable She has had seven temporary stays

Reply to questionnaire (by husband)—I consider temporary stays of great assistance They have enabled me to take on a part time job and I feel ten years younger ' When my wife returns home she is much easier to manage She volunteers to wash the dishes and does so successfully She is still chair fast but is more reconciled to her disability She likes going into hospital as she feels it helps me She is not afraid any more as she knows that she will not be kept in hospital permanently

---

[1] Sheldon J H The Social Medicine of Old Age London 1945 p 197

Case 3 —Mrs C, aged 89, had fractured her left femur in 1950 She had achieved full weight-bearing in 1951, but then lost interest and often fell Her son kept her in bed as he felt she would fracture her good leg She became difficult and incontinent, and dirty in her habits Her son, much attached to his mother, had spent part of his income in getting help for her Her son's wife was overwrought and anxious and this tension was communicated to their only son who was working for his 11+ examination When the patient was seen she was bedfast, with disuse atrophy of the right leg and flexion contracture of the left

Reply to questionnaire (by son) —Temporary stays of very great assistance The procedure has saved my wife from another breakdown in health Giving her six-week periods of rest has changed the atmosphere in my home to the benefit of my wife, my son, and myself We are all amazed that my mother can now walk again When she comes home for a temporary stay our nights are undisturbed My mother is very happy with the arrangement as she benefits from the company of other old people and the change in surroundings We are all very grateful and hope that this service will be extended to others

Replies to 70 questionnaires have been received and they are all couched in like terms They may be summed up in a phrase used by the daughter of a patient She says "The temporary stay procedure has made a difference to me between existing and living" It is worth recording that 30% of these patients were cared for by daughters Reports from general practitioners are equally heartening Only 3 patients have so far become "permanent" after the fourth temporary stay, as the domestic situation had changed In the present series 67% of the patients continue to enjoy the arrangement

Observations on the Experiment

The experiment owes its success to a therapy catering for the emotional and social needs of the patients and their relatives, and not merely the physical rehabilitation of the patients The latter is always tried, but the results are disappointing, for these patients are suffering from disabilities of many years' duration Teaching them to live with their disabilities is an important part of therapy

When these patients are first seen in their own homes they seldom know how much anxiety they are causing in the household They have one fear—that the relatives no longer want them and that they are going to be tucked away in hospital and forgotten When the temporary stay is explained to them they are at first suspicious but eventually agree to try it

Within forty-eight hours of admission social contacts are made, conversation flows, and experiences are exchanged The morale of the newcomer is quickly raised as she hears about the facilities available and the part she will play in the kitchen activities When she is told by several members of the group that they will be going home in a few weeks' time for a temporary stay she knows that this too will be her experience The aged infirm are often lonely and welcome those of their own age group with parallel memories, activities, and capacities, they feel out of place in a household where everyone is younger and active When relatives visit the unit they find the patient an entirely different person, who is pleased to see them and expresses, perhaps for the first time in years, how much she likes them They react accordingly and make the patient feel that when she returns home for a temporary stay she will be accepted as a member of the family circle Family affection is thus preserved A burden has been lightened and a sense of responsibility maintained

Sheldon[1] estimated that 7 7% of the old people were causing great strain on the younger generation, in my own series the figure is 13% The burden will, I believe, continue to grow, because there will be more aged in the community Incapacity, rather than old age, is its true measure, and no matter what medical and social progress is made, relatives will be required to share it Geriatric centres could, in the way we are trying, give intensive medical and temporary social care to a considerable proportion of infirm patients, and reduce the need for long-stay annexes

Summary

The aged infirm are increasing in number, and the stress imposed on relatives caring for them is not fully appreciated The measure of this stress can be assessed only by a domiciliary visit In 1955, 902 such visits were paid, and in 120 (13%) cases stress in the home was the principal reason why admission to hospital was sought Many relatives only wish the burden to be lightened and the temporary-stay procedure, which is described, does this

A few of our case histories illustrate the type of medical and social problem, and replies to a questionnaire sent to relatives show that a great need has been met

---

THE GAZIER PLAN

FROM A PARIS CORRESPONDENT

SOMETHING seems to have gone wrong with the game of musical chairs which has for so long been a part of French politics the present government is still in power, after more than a year Unless the music stops very shortly—and this seems unlikely—parliament will amend the 1945 law governing the French social security system Already the proposed amendments—the "Projet Gazier" as they are called after the Minister for Social Affairs—are being studied by the relevant government departments before it is discussed by the Assemblee Nationale in the next few weeks The medical profession is up in arms against it the Confédération des Syndicats Medicaux, the French equivalent of the B M.A, has unanimously adopted a resolution flatly rejecting it, l'Ordre des Médecins, the French General Medical Council, has opposed it, and the venerable Academie de Médecine has "denounced the danger of administrative regulations which could jeopardise the proper treatment of patients and the mission and dignity of the medical profession"

What is it all about? French medical practice is based on four principles the patient should be free to choose his doctor, the doctor should be free to prescribe without limitations of any sort, strict professional secrecy should be maintained, and the doctor should be at liberty to decide his fee with the patient It is around this last principle that the battle is raging

THE PRESENT SOCIAL SECURITY SYSTEM

In 1945 the original law on social insurance (1928) was recast and made more comprehensive social insurance became social security Unlike the British system, French social security rejects the principle of universality, but where it operates (in the large majority of cases) it covers all needs "from the cradle to the grave" It even anticipates the cradle by providing financial incentives to have large families

In the matter of medical benefits, the principles governing the original law remained unchanged The patient pays a fee to his doctor, whether physician or surgeon, for each item of service, and he is reimbursed 80% of a theoretical fee given on a scale established by the social security organisation These theoretical fees are supposed to be fixed by agreement between the local branch of the social security organisation and the local chapter of the medical association In practice, agreements have been reached only in a few instances, because the social-security organisation insists on fees which the doctors say are much too low Since the law provides three categories of exemptions for doctors, most patients are reimbursed for only 50–60% of their outlay for a general practitioner and less for a specialist—except when they go to hospital

THE ORIGINAL PROPOSALS

The present government, supported by trade unions, holds that the existing system needs reform, and in the minds of most doctors the cure proposed will destroy medicine as a liberal profession Clumsy handling by the government has made matters worse

The government's key idea is to establish a precise scale of fees and to make it compulsory for all but 15% of doctors, who will be free to charge what they want on the understanding that their patients will not be reimbursed for anything except medicines The minister feels that by sacrificing "freedom for fees" he saves the other three principles which, in his opinion, are more fundamental

Most French doctors think it is extremely difficult to codify rigidly medical consultations, since each is essentially different If fees are standardised, doctors will be obliged to see more patients to maintain their present standard of living and in consequence patients will receive poor attention The older and more experienced man will be unable to charge more and the younger man with higher qualifications will likewise be handicapped The French feel strongly that the family doctor is the first line of defence against disease The more he can tackle, the less will be referred to hospitals, which should be reserved for difficult cases or special treatments The French medical profession is united in the belief that nothing must be done that will lower the standard of general practice and lead to "assembly-line" medicine

What of the 15% of doctors who would be outside the scheme? The profession believes that the creation of a special category whose services will not be reimbursed destroys the principle of "freedom of choice" All consultants will be in this category, and it is argued, therefore, that all but the wealthy will be discouraged from seeking a second opinion by private consultation

Another difficulty is being foreseen France is the country of competitive examinations, and there are many hurdles that the would be consultant must clear, what will happen, it is being asked, to those with excellent training and long experience but who have not made the grade simply because there were not enough jobs to go round? They will have to go into general practice without being allowed to charge more than their colleagues who took up practice immediately after qualifying Will this not deter the younger members of the profession from taking the examinations? Moreover, as many declare, a flat 15% cannot fairly be applied to all regions of France, since there are more consultants in university towns than in the country

Among other less fundamental objections to the Projet Gazier is the suggestion that it would be better to hitch the agreed fees to a sliding scale based on the cost-of-living index and the general wealth of the country Few doctors find solace in this plan

SECOND THOUGHTS

The final draft has not yet been submitted to parliament, and already changes are being made For example, it is now suggested that patients of "free fee" doctors be refunded on the basis of the legal rates, and that the "free fee" doctors will represent 15% of medical practitioners for the whole of France and not by region Moreover, provision is proposed for the recognition of specialists and consultants who may not possess the relevant degree or diploma but whose personal merit warrants recognition Finally, the latest plan is that doctors' fees will follow the cost-of-living index (which is manipulated by the government) and the purchasing power index established by the Institut National de la Statistique (which is free from manipulation) No doubt the final draft will be further amended by parliament

THE PATIENT'S VIEWPOINT

For the patient, who is also a taxpayer and a contributor to the social security scheme, some of these discussions seem theoretical He pays his dues and would like to get his money's worth "If this scheme is adopted," he asks, "will I be refunded 80% of my doctor's bill?" The answer must be an emphatic "no" The deficit of the social security system is increasing yearly and nothing short of reorganisation will stop it Having tasted military medicine, he dislikes anything that resembles the front line "sorting" type of medicine if that is what the scheme will amount to, he does not want it He does not like hospitals very much and prefers to be nursed at home He knows that hospital medical care will be the very best, but somehow he dislikes the common ward He realises that the social security system needs overhauling, but in spite of a cumbersome administration it works well enough—if only he were refunded more

MORE THAN FEES

No one disputes that something must be done to streamline the French social-security system, and many feel that major surgery is needed As the doctors see it, however, the proposed reform is tinkering with the fundamental problem it is an attempt by the government to lighten the sick man's burden—at the doctor's expense The medical profession interprets these moves as more than a challenge to their fees France is one of the few Continental countries where medicine has retained its traditional liberal character, and the great majority of French doctors will resist any effort to change the existing pattern

Medical Education

THE UNIVERSITY HOSPITAL

DAVID H PATEY
M S Lond, F R C S
SURGEON TO THE MIDDLESEX HOSPITAL, LONDON, AND DIRECTOR OF SURGICAL STUDIES IN THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

THE close association of universities and hospitals is a late development in this country as compared with in Germany and the United States There is general agreement that the meteoric advance of medicine in America in the present century is due largely to its linkage with the universities, and this is one of the reasons for the current trend towards strengthening similar university linkages in Britain It would be wrong to pretend, however, that the problem is an easy one, or that it is automatically solved by the application of a formula which works in other countries where the historical background and present conditions are different It is easy too to fall into the error of repeating clichés, or using words such as "research," "teaching," or "duty to one's patients" merely as slogans, or even as weapons with which to beat one's opponents The brief observations which follow are merely an attempt to define and clarify some of the problems

Some Definitions

A hospital is "an institution for the care of the sick," and a university (to paraphrase slightly the words of Adlai Stevenson) "an institution whose function is the search for truth and its communication to succeeding generations" The functions of the hospital and the university in a university hospital are thus complementary rather than antagonistic A hospital's work is concerned with the present, a university's with the future The hospital's primary duty is to the sick people who seek its aid The university is largely responsible for the doctors, and hence for the medicine, of the future

So far from there being a conflict between these two objectives, the long-term perspective associated with the university ideal should result in a higher standard of care for patients , and the general experience shows that it in fact does

Integration

The problem thus becomes one of integration It must be recognised that mere placing together does not constitute integration It may even mean the reverse, as illustrated, to take a political example, by the history of the modern State of Israel A similar state of affairs may obtain when a university department is established in a hospital The teaching hospitals of this country have a long and honourable tradition, built on the democratic ideals of individual freedom and responsibility Many of those working in these hospitals fear the establishment of an authoritarian professional system on the Continental model The reaction to this fear may be the isolation and insulation of the university's clinical departments Though they may do excellent work under these conditions, they obviously fail to have the influence they should on the hospital as a whole The remedy would seem to be for the university to recognise the strength and value of the democratic tradition in the teaching hospitals, and seek to harness these qualities in the service of the university ideal. The university department should be neither authoritarian nor insulated, but rather coordinating and catalytic

Research

Research is usually divided into pure and applied Conant [1] gives, as the main examples of this subdivision in the modern world, university research, which is primarily concerned with the discovery of fundamental principles, and industrial research, which is primarily directed towards the solution of immediate practical problems Medicine is an applied science, and therefore much of medical research must approximate to industrial research Since there is no lack of immediate practical problems in all branches of medicine research in a university hospital should be regarded as a general activity in which the university department has a special rôle Apart from the investigation of its own practical problems, the special functions of the university department are the providing of posts for, and the training of, research-workers, and the search for fundamental principles To perform these functions, the department needs research facilities and research assistants under its own control, as well as a liaison with the preclinical and hospital research departments

Teaching

The teaching hospitals of this country are by tradition regarded as primarily concerned with undergraduate medical education—the term “ primarily ” often being interpreted as “ almost exclusively ” As a result, little attempt has been made by the universities of this country to define and control postgraduate medical education This is in striking contrast with the United States, where, since the end of the last century the universities have closely guided the course of higher medical education Probably the attitude of the teaching hospitals of this country has been determined by their looking on postgraduate education mainly as a matter of cram courses for higher examinations, with all the interference with undergraduate education that these courses often cause, whereas such courses really constitute a relatively unimportant part of postgraduate education A greater interest in postgraduate education by university hospitals would be fitting to the position of this country as the heart of a great commonwealth Moreover, some control by the universities of the appointment of registrars may be the only solution of the registrar problem

As regards undergraduate education, there are large questions of principle content and technique which I shall not broach here But the point to emphasise is that the university department should be concerned not merely with teaching in its own unit, but with the mobilisation of teaching ability and material in the hospital as a whole As regards postgraduate education, the special functions of the university department should be the provision of facilities for and the encouragement of research

Suggested Academic Organisation of University Hospital

Much of the voluminous writing on medical education, while enunciating ideals which meet with general approval, is vague when it comes to their application An attempt will therefore be made here to outline a scheme of integration between university and teaching hospital, starting from the principle that the democratic traditions of the teaching hospital should be preserved but its relations with the university strengthened

Under the chairmanship of the dean of the medical school and responsible through the academic board to the school council, the clinical professors might constitute a clinical education committee Under this committee, each clinical professor would be chairman of a medium-sized subcommittee, widely representative of the clinical teachers in the corresponding subject, and advising on all aspects of education—e g , lectures, the full use for medical education of the clinical material in all departments of the hospital, and the organising of staff meetings This last function, and the fostering of the tradition of all grades of staff assisting at such meetings, should be regarded as especially important To emphasise his coordinating function, the full title of a professor should be “ professor of medicine, and chairman of the medical education subcommittee ”—and similarly for the other professors The above committees should meet regularly, but ordinarily this should not be necessary more than twice a year Owing to their representative character, the advice they give through the dean to the school council is not likely to give rise to difficulty when conveyed by the school council to the hospital

The University Unit

Some such organisation as the above should ensure that the university unit exercised the maximum catalytic and coordinative influence on teaching and research in the hospital as a whole This would be achieved too by a form of partnership, and without impinging on the individuality and resultant vitality of the other units As regards the organisation of the university unit itself, it should have some additional beds as compared with other clinical units (chiefly to provide clinical facilities for its research assistants), and facilities (if possible close to the wards) to enable it to fulfil its special functions in clinical teaching and research

Private Practice

Finally, brief reference must be made to private practice Too much importance has probably been attached to this question by the universities in the past indeed there has been a danger of a clinical professor being defined merely negatively as someone to whom private practice is forbidden A clinical professorship should clearly be substantially a whole time job, but the desire of the university to protect him from private practice sometimes contrasts with the excessive calls the university often makes on his time for administrative work, examining, and visiting The pros and cons of allowing some limited private practice have often been argued, and I shall not go into them here In my opinion, however, the main disadvantage of cutting off the clinical professor from all private practice is that it makes him different from his colleagues in kind, and not merely in degree, and hence makes integration of the university department and the hospital as a whole more difficult If the universities would adopt a less rigid attitude, this would give the teaching hospitals the opportunity to experiment, without their adopting such extramural devices as the appointment of directors rather than professors The present power of the universities over medical education is so great, if they choose to use it, that they should have no difficulty in reviewing and controlling experiments carried out under their ægis

---

[1] Conant J B The Citadel of Learning New Haven 1956

CONCLUSIONS

The universities should devote their attention not merely to the establishment of university units in teaching hospitals but to their integration with the hospital to produce true university hospitals The Continental authoritarian professorial system is unsuited to the democratic medical traditions of this country, and attempts to introduce it are undesirable On the other hand, the non integrated professorial unit, though capable of excellent work, does not by itself make for a true university hospital The time is ripe for universities to encourage experiments, aiming at the establishment of such integration

Public Health

PEDICULOSIS CAPITIS

A COMPARISON OF TWO REMEDIES

I D M NELSON
M B Belf, D P H
DEPUTY MEDICAL OFFICER OF HEALTH, COUNTY BOROUGH OF BRIGHTON

S A CROMIE
B Sc (Pharm) Belf, M P S N I
INDUSTRIAL PHARMACIST

IT seems strange that, despite progress with insecticides, pediculosis capitis should still be so prevalent among school children Official national figures showed that of those examined in the schools of England and Wales in 1953 1 9% were found to be verminous[1] Beare[2] points out that the prevalence varies, and that often more than half of a school population are infested He quotes a fairly constant annual figure of 8% from the total school population of Belfast

One of us (I D M N) has circularised principal school medical officers of county boroughs of England and Wales The information they have kindly supplied shows that in 77 county boroughs for the four years 1951–54 the proportion of children with nits or lice ranged from 0 5 to 22 9%, the averages being 6 9%, 6 8%, 6 2%, and 5 5% in 1951, 1952, 1953, and 1954 respectively For 34 counties the corresponding averages were 2 7%, 2 7%, 2 2%, and 1 9%

In considering such figures one must recognise differences of definition In some areas the presence of one nit classifies a child as "dirty," excluding it from school until clean, whereas in others a child is not "dirty" unless lice are present

The principal school medical officers of the county boroughs also told us what preparations were used in their school health service Taking the one mentioned first in each return (for many mentioned two or even three), we found that the following were those most commonly used

1 'Suleo' hair emulsion containing 2% dicophane (D D T) and 1% pyrethrums *B P C*
2 'Lorexane' concentrate, containing 1% gamma benzene hexachloride ('Gammexane')
3 'Lorexane' head lotion, containing 0 2% gamma benzene hexachloride
4 'Esoderm' medicated shampoo, containing 1 0% dicophane
5 Dicophane (in various bases and strengths)

TRIAL OF PREPARATIONS

Over 400 infested Brighton school children were treated alternately with either suleo hair emulsion or esoderm medicated shampoo Bearing in mind the difficulty some workers[3] had experienced in obtaining similar results with the same preparation in different parts of the country, it was decided that all the examinations and re examinations should be done by one nurse and all the shampooing and applications by another, both had had long experience in this work This ensured that all the classifications of infestation would be reasonably constant and that the two preparations would be used under similar conditions During the trial the results were computed after each hundred cases or thereabouts, and they remained fairly constant throughout No choice of preparation was allowed, and within the same family children were treated with different preparations

The parents were asked, in a letter from the school medical officer, not to interfere with their children's hair in any way, except as recommended by the manufacturers for each preparation All the children were re examined after two weeks

RESULTS

It appears from the table that esoderm medicated shampoo gave better results than suleo hair emulsion

Of the four common preparations mentioned above esoderm is the only one which washes the hair as well as attacking the vermin in it It has, therefore, the advantage that the infested person can return to the community at once with a "clean" head

Esoderm was probably the most difficult to use clinically, in that it entailed a shampoo and the hair had to be dried It was found, however, that the detergent base assisted in the removal of nits

GENERAL OBSERVATIONS

In comparing published statistics, a difficulty arises because the number of infested children can be expressed either as a percentage of the total number of examinations or as a percentage of the school population at the time Moreover, when figures are given, the procedure of inspection should be stated In some schools head inspections are made at the beginning of term while in others they are as frequent as once a month Again the whole school may be inspected or only the junior department

Some local authorities accept full responsibility themselves for cleansing, others place the onus entirely on the parents In our opinion, the onus should be placed on the parents, with guidance from trained staff Curnow,[4] like some others, uses the threat of court action for persistent offenders, but most medical officers prefer to leave the matter in the hands of staff who, by instruction and persuasion, can usually make the most difficult families see reason The families in the lower

RESULTS OF TREATMENT WITH TWO PREPARATIONS

	Sulco		Esoderm	
	Before treatment	After treatment	Before treatment	After treatment
Nits	90 (43 2%)	28 (13 4%)	125 (55 8%)	14 (6 [illegible]%)
Many nits	75 (35 9%)	2 (1%)	69 (30 8%)	1 (0 4%)
Lice and many nits	27 (12 9%)	1 (0 5%)	14 (6 2%)	—
Lice and nits	14 (6 7%)	1 (0 5%)	6 (2 7%)	—
Few or very few nits	[illegible] (1 3%)	53 (25 1%)	10 (4 5%)	34 (15 2%)
Clean	—	126 (60 3%)	—	175 (78 1%)
Total	209	209	224	224

social classes, and problem families, may often be the most cooperative, making full use of the services provided, in such situations particularly, it is important to have the right kind of adviser

It does not matter whether the staff who undertake this work are trained nurses or not, provided they have the right personality School nurses are scarce, but most authorities, certainly in urban areas, should have no difficulty in finding suitable people to carry out the work In this field there is an absolute argument for the nursing staff of the school health service and the public-health service to be one

Reinfestation takes place mainly in the family circle, the same children requiring treatment time after time Hence, some attempt should be made to examine and treat the other members of the household In attempting this it is very helpful to be able to advise the use of a preparation which is acceptable to all members of the household In our experience there is no doubt that a preparation which washes the hair as well as disinfests is the one of choice

We should like to thank Dr W S Parker, medical officer of health for Brighton, for facilities for the trial, and Dr F Langford, county medical officer of health for East Sussex, for help with the figures from county councils

Life Tables

The life tables volume[1] of the Registrar-General's Decennial Supplement for England and Wales, 1951, contains English life tables no 11, prepared by the Government Actuary The tables, published for males and females separately, are based on the 1951 Census populations and on the mortality experience in England and Wales as a whole in the three years 1950–52

In addition to the main tables for the country as a whole, life tables on an abridged scale are published for Wales and for Greater London The expectation of life of a boy at birth has increased by nearly 15 years in the past 40 years, for a girl the increase is more than 16 years These increases are largely the result of improvement in infant mortality For men aged 60 the expectation of life on 1950–52 mortality is about 14$^3/_4$ years, an increase of only $^3/_8$ of a year on the figure 20 years earlier, whereas for women it is now 18 years, an increase of 1$^1/_2$ years Alone of all the major conurbations Greater London experienced lighter mortality than England and Wales as a whole The sharpest geographical contrast was between the Merseyside conurbation, with mortality for men 21% above the national average, and the Eastern region (mainly rural), with mortality for men 14% below the national average

Medicine and the Law

Could a Child be Born ?

FROM A CORRESPONDENT

THOUGH the courts ought not to feel themselves bound to give effect to every scientific thesis, yet clearly the Law should not so ignore medically accepted facts as to violate common sense Recent recommendations of the Law Revision Committee (a body consisting of judges and practising and academic lawyers who consider matters referred to them with a view to legislative reform) aim to make more realistic certain aspects of the Rule against Perpetuities

Though generally the Law was sympathetic to property rights and encouraged freedom of disposition, yet it early recognised that no good came from allowing testators and settlers to tie up their land through generations unborn Otherwise dynasty-forming ambitions would prompt patriarchs of the past to settle their land first on living children, and then down through their children's children so that successive estates might spring to life in the future and no one have the power to break the shackles on free transfer The Rule as developed provides that where an estate is to arise in the future it must vest within the perpetuity period This is taken as the duration of a chosen life which exists at the date of the testator's death (if the settlement is by will) plus 21 years Any life may be chosen including one *en ventre sa mère*, or even a number of lives so long as they can be traced so that it will be known when the last life ends At the end of the 21 years a period of gestation may be added The future estate must vest—if it is to vest at all—inside this period If there is any possibility that it will vest outside the period then the gift fails So keen was the law to keep settlers within bounds that it would not even allow a period to wait and see whether in fact the estate did vest in the period or whether the unlikely chimera would appear

One assumption made for this purpose (though it is not always made in other issues) is that of life long fertility Wherever a woman might have a child who would affect the vesting, then a doctor cannot be heard to say that after a certain age, however conservatively estimated, no child could be born Sarah is the exemplar and evidence of disabling deformity including, semble, removal of the uterus would not help a beneficiary to show that there was no chance of a rival claimant

Thus in *Re* Dawson 1889 a gift was made to the children of the testator's daughter (D) who attained 21 and the grand children of D who attained 21 born of D's children who died under 21 A hypothetical grandchild might attain 21 outside the period, if D had a child after the testator's death who died under 21 leaving children who in turn might become beneficiaries at 21 The birth of a child to D after the testator's death was improbable since D was 60 when the testator died, but it was held that the mere improbability that D would have a child was not enough to close the class entitled, and so the whole gift violated the Rule against Perpetuities

The cases have been concerned with a woman of 62, spouses of 66, and, in Jee *v* Audley 1787, with spouses both 70, yet it was said here to be of great inconvenience and a dangerous experiment to allow conjecture on such matters as their ability to have children, and evidence was excluded It was said in *Re* Dawson that similarly medical evidence of incapacity for other reasons than age would be excluded, and it could not be shown that a man was sterile

If the new recommendations are adopted they will make changes in assumption without affecting the main objects of the Rule It is suggested that a court shall presume that a woman who has reached the age of 55 is not capable of having a child, and that a boy or girl under 14 *shall similarly for the purposes of the Rule* be regarded as lacking capacity This will allow the courts to decide when the settlement or will is in dispute that a woman as in *Re* Dawson will not have future children so that the property will be capable in law as well as fact of vesting within the period But, since the unusual may happen, this presumption should be rebuttable by proof that a woman over 55 is pregnant at the time of the proceedings when the validity of the vesting must be decided Similar evidence may be brought when, for *example, a girl of 13* can be shown to be pregnant But though this may be thought to be a more likely eventuality than the other it will perhaps not often be invoked, since legitimate children are usually referred to, and where English Law is to govern the question, a child under 16 cannot have a legitimate child

Thus medical evidence will be required sufficient to satisfy the court that the presumption should be rebutted at the time when the validity is in question, and the court's decision shall be accepted even if subsequent events *prove it to* have been wrong—though without prejudice to the child's right to property not in the event void for perpetuity

It now remains to be seen whether Parliament adopts the recommendations

In England Now

A Running Commentary by Peripatetic Correspondents

February fill-dyke has done well so far My gardener's anxious voice when I drive away in the morning, "Go steady through the water, doctor" reminds me of our old coachman as we set off on our ponies for the meet "Now Miss Glady, don't you 'arrap 'er about"

Last night I was safely at home when a knock at the door revealed an agitated young man with bare feet and trousers rolled up above his knees, standing in the porch

"Can I telephone for a tow? The road's flooded"
"It does"
"They don't give you any warning"
"No they don't"
"I've driven the car right into it"
"So have I before now"
"It's very cold"
"I always carry wellingtons"
"My father's in the car, I hope he won't try to follow me"

So did I, but while the young man was wrestling with "inquiries" and the intricacies of our country telephone, father arrived, roaring the engine, hooting and spluttering, with smoke, steam, and a blaze of headlights They left, this time with a warning, "There's another flood about 400 yards up the road"

* * *

From a stay at home doctor's postbag

I had a wonderful time in West Australia After a fortnight in Borneo, where I was in the jungle doing some work on the infertility of Muruts (since the British Government has stopped them head hunting they have lost their pride and become dirty, so when they get married at an early age, after an abortion or childbirth, the women become septic and get a parametritis, hence sterility), I flew on to Darwin where I landed in the middle of the night

In spite of what is said about Darwin I liked it I spent two days there dodging the flies and then flew on to Port Headland If you know where Port Headland is, you will realise it is on the edge of the outback I flew round with the flying doctor there for about a fortnight in a small aeroplane that went backwards when the wind blew It also went in every direction, up and down and sideways, but I penetrated all over the outback I went into some very distant places, including Marble Bar, Nulgaine, and Jiggilo, which, in case you don't know, is on the edge of the desert

After that I flew down to ———, had a very interesting two days with the local doctor, and then spent twenty four hours whaling I took some excellent pictures of this After I arrived back about midnight, went to my pub, and had got the smell of whale oil off, it was obviously too late to ring the doctor to thank him I was due to fly off the next day, but just as I was about to set off news came through that he had been drowned in tragic circumstances With two friends he had gone fishing and had been swept away by the sea

Clearly I couldn't fly out of ——— in circumstances like this, so I stayed on and took over the local practice for nearly a week This included two obstetric cases and one infanticide Fortunately no major surgery was needed, I shouldn't have been able to do it if it had been, but I had some difficult and interesting medical cases

Eventually I arrived in Perth thoroughly exhausted, and caught the ship which called up the west coast of Australia We left Australia at Broome, and forty eight hours out the ship's doctor burst into my cabin at 7 A M and asked me to see a man with a perforated gastric ulcer After I'd collected my wits I went along to a fellow passenger's cabin and after considerable cogitation announced that I didn't think he had a P G U but hepatitis—possibly early infective hepatitis However, I spent a very miserable day thinking that the ship was steaming further away from medical aid and I was cooking an acute death I must say I was glad to wake up the next morning to find the patient still alive and with definite localising signs Eventually he turned out to have an amœbic abscess, a diagnosis which I did in fact suggest later in the course of the voyage

That I think is all the news except that I may be in London in February on my way to New York, but it will only be for about two days

* * *

Tremors of the human body, whatever their cause, are easily recognised Earth tremors are different Some ten years ago, I was on holiday when, at 8 o'clock in the morning, my bed—in fact my whole house—shook violently, although I was some 55 miles south of the area where the tremor was greatest My second experience was ten days ago when I was doing outpatients in a town some 50 miles south of Derby The room I was in felt as though it was being bumped from side to side for about three seconds No-one took much notice even when I said to my house-physician "That is an earthquake!" The sister registered incredulity but greeted me next morning with an apologetic "You were right!"

* * *

I don't think we have done ourselves any good by pinching the title of doctor You only have to look up the *O E D* to see how its meaning has become vulgarised and of course everyone knows that the vet doctors a *tom-cat* *Then we have to contend with the frightful* people who greet us with a hearty "Hello, Doc!" By all means in the future let us be known as physicians Hello, Phiz!

* * *

The police had considered that my evidence might be needed in the case So for three hours before and two hours after the luncheon interval I sat in the public seat my thoughts uneasily preoccupied with the debt of work accumulating in my absence The case was dismissed, inside of ten minutes, without any contribution from me

At teatime my wife was reading aloud from the correspondence columns of the local paper Several readers who had been kept waiting unduly long at doctors' surgeries seemed to be asking for an appointment system "I see their point at present with unusual clarity," I said as I departed to do the sizeable list of visits that would have been completed in the morning, had circumstances allowed

* * *

Point the forceps up a little, Barlow Thank you so much Cut Shorter! A little shorter, Barlow, don't be afraid I am very good tempered About 1/8 inch Ah! I see our ideas of absolute measurement are quite, quite different Cut the gut just sufficiently far away to keep the knot happy

Now I know what you mean, Sir

Good! I felt confident that in time I would find a formula which would appeal to you And now if you will, just for a moment, take your head out of the field of operation Thank you, Some day, Barlow, and quite by accident of course, I shall scalp you Nurse, wipe Mr Barlow's brow We have no evidence to show his sweat is sterile Now there's an idea for your M D thesis—*The Flora on the Surgeon's Brow*—rather like the opening bar of a Sitwell poem

The Flora on the Surgeon's Brow
Oleum Olei, Olea, Oleon

I once wrote a poem in my student days a rather sad little piece I think I can recall the first line "Why, Oh why did the wicked Hormone?" which is prettily scanned, don't you agree?

Indeed, Sir, rather like *Balder Dead*

I see no relevance *My* verse was serious

Yes, Sir

If you lean very heavily on the patient's chest, Barlow he stops breathing Have you noticed?

Sorry, Sir!

Cut Shorter! No, not off Just shorter Again Cut it's really quite extraordinary once you get a pair of scissors in your hand, Barlow, you change from a very decent quiet young man into a thyrotoxic barber Relax my boy Hold your breath and count five hundred very slowly

Yes Sir Sorry, Sir

Don't apologise An apology establishes guilt which will in time, give you a complex of inadequacy When are you going on holiday, Barlow?

On the 24th, Sir

I shall miss you my boy We shall all miss Mr Barlow, won't we sister?

Letters to the Editor

BRONCHIAL CARCINOMA

SIR,—Mr Nicholson and his associates (Feb 9) deplore the average delay of six months between the onset of symptoms and the attendance of patients at their clinic They misguide us when they state that "we must strive to persuade the public to recognise and take heed of these symptoms early, and not to neglect them for six months"

The delay in diagnosis of carcinoma of the lung is not due to the failure of patients to report their symptoms to their doctors It is largely due to the failure of the medical profession as a whole to diagnose carcinoma of the lung at an early stage This long delay is experienced in almost all surgical centres It is due to the essential difficulties in diagnosis, which requires special techniques available only in thoracic surgical units The present tendency for general practitioners to refer chest cases to chest clinics, which have evolved from the old tuberculosis dispensary, in order to get an X ray, has contributed largely to the delay

An analysis of the causes of delay in *referring the* 135 cases submitted to operation for carcinoma of the lung at the London Hospital in 1954 showed an average delay from first symptom to attendance at the department of thoracic surgery of 6 4 months This delay was made up as follows

From first symptom to consulting general practitioner.	1 5 months
From seeing general practitioner to seeing chest physician	1 1 months
From *seeing chest* physician to seeing chest surgeon	3 8 months

A further analysis of these figures revealed that the average delay between physician and surgeon was 2 months for those cases which proved to be inoperable at thoracotomy, 4 months for those who had a pneumonectomy, and 5 5 months *for those* who had lobectomy. The delay was greatest in those most likely to benefit from surgery

The difficulties in diagnosis are the real problem Diagnosis requires special techniques available to surgeons but not to most physicians If general practitioners could have chest X rays for their patients independently of consultant physicians the delay between first symptom and operation might be appreciably shortened General practitioners who suspect that their patients have carcinoma of the lung should be encouraged to send them direct to surgical centres There are enough fully trained thoracic surgeons to deal with the problem There could be a great economy, a benefit *to patients*, and less frustration if there existed an independent radiological service so that general practitioners could have a direct report on which they could exercise their own responsibility Radiology is now an essential part of clinical examination

London W 1 **VERNON C THOMPSON**

TOWARDS PREVENTING SUICIDE

SIR —Dr Parnell and Dr Skottowe (Jan 26) have raised an important issue and have re emphasised the warning signs of possible suicide I am always put on the alert when ideas of guilt, self depreciation and self-accusation, associated with *tension* and agitation, are in evidence and if the patient does not get any relief from unburdening Again, if a patient is preoccupied with one organ or one system and is convinced that the disorder is serious, then one should realise that he is a potential suicide

It is a fallacy to think that the patient who talks about killing himself will not do so Insomnia is also of great importance, especially if the person is very concerned about it Patients often have grave doubts about the hypnotics prescribed they fear that drugs will damage their brain It is well to spend some time explaining to the patient that the medicine prescribed can be successfully dealt with by the body, and cannot possibly cause harm Dr Parnell and Dr Skottowe did not mention the Rorschach test, which is said to be a useful addition to psychiatric examination in predicting suicidal tendencies Many papers on Rorschach findings in cases of attempted suicide have appeared within recent years It has been pointed out that preoccupation with heavy grey colouring of the blots, usually on more than one figure and almost always on fig 4, suggests suicidal trends Marguerite Hertz, of Cleveland, Ohio, believes that Rorschach testing detects more suicidal risks than are recognised by behaviour signs or other symptoms

In regard to the case quoted by Dr Wilkinson (Feb 9) it is interesting to note that in Rorschach studies there is a suggestion that outwardly directed aggressiveness and hostility are less characteristic of suicidal patients While I agree with Dr Sawle Thomas (Feb 9) that many depressed patients are successfully treated by outpatient electroconvulsion therapy, the thorough going psychotic depressive with suicidal ideas is a *serious risk*, and should be treated in a mental hospital In my experience it is during the period of recovery, when the emotional field is still variable, that suicide occurs, extra caution should be exercised and it is better for the patient to be away from home

Dr Lawrence (Feb 9) mentions the important relationship between alcoholism and suicide I regard alcoholism as a form of physiological suicide Certain patients have unconscious drives which allow them to kill themselves by alcohol It is not surprising that on occasions the process is speeded up by overt attempts which are often successful Of course, the causes given for self-destruction are much too contradictory to be of any use *in understanding the suicidal drive* Sometimes it may be easy to understand how persons suffering from psychotic and nervous illnesses can commit suicide, but it is very difficult to understand the unexpected suicide The great majority of suicides are "normal" people and the reasons given for their attempts, such as problems of love, finance, or bereavement, are merely "triggers which have fired the loaded gun"

Severalls Hospital
Colchester **ROBERT H F SMITH**

SIR —The article by Dr Parnell and Dr Skottowe, and the correspondence which followed it, seem to assume that the prevention of suicide is always desirable Is that assumption justified? Dr Pullar-Strecker reminds us (Feb 9) that 130 years ago it was legal to bury suicides at a cross roads with a stake through their bodies Presumably that reflected the attitude of very many people at the time But public opinion has moved far since then, and I suggest that it is still moving

Many have come to realise that it is utterly hypocritical to condemn the individual suicide on the ground of the "sanctity of human life" while all the nations are prepared to send their young men to die in war And many are frankly questioning the too facile assumption that suicide always betokens an unsound mind Are we not moving towards a time when many of those who, by reason of the infirmities of old age, are no longer able to make a worth-while contribution to the community in which they live and to enjoy life, will fearlessly ask themselves whether it is not better to "cut the painter" rather than join the ever-increasing host of those waiting to die in old people's homes, mental *institutions*, or the homes of kindly (or not-so kindly) friends and relations? It seems to me that the social and economic stresses and strains of our rapidly ageing population must inevitably lead to such questionings, and, as a probable result, to a rising suicide rate, at least among the old It would be of interest to know if the high suicide rates of Switzerland and Denmark show any evidence of such a trend

Suicide unrelated to old age is of course another story, and requires different consideration But here again I suggest that we should be on our guard against the assumption that the premature termination of life is necessarily an evil thing, and must denote unsoundness of mind By all means let us try to prevent the suicides that derive from temporary depression or other form of mental derangement, but let us also move towards a more reasonable public opinion on the basic right of human beings to have a say in the disposal of their lives There would seem to be a place for some measure of death control (subject to proper safeguards) as well as of birth-control

Farnham Royal, Bucks LEONARD COLEBROOK

STEVENS-JOHNSON SYNDROME

SIR,—In his paper of Feb 9 Dr Short rightly points out that in Stevens-Johnson syndrome a fatal outcome should be uncommon Both in major and minor forms, this often recurrent syndrome of skin, mucous membrane, and sometimes pulmonary lesions tends to occur *d'emblee*, and, though there may be relevant antecedent infection and treatment with sulphonamides or other drugs, the proving of their specific relation to the onset of this illness is rarely possible Early recognition and treatment of the severer cases with adequate amounts of cortisone or corticotrophin (A C T H), with or without antibiotics, has appeared in our cases to cut short this distressing condition so that fatalities have not occurred

But the term Stevens Johnson syndrome is being used as a firm, if descriptive, diagnosis in more serious and fulminating conditions such as acute systemic lupus erythematosus, severe sulphonamide sensitivity reactions, and polyarteritis nodosa—of which Wegener's granulomatosis is probably a variant—in which skin, mucous membrane, and pulmonary lesions form only part of a more general disease The hæmorrhagic, necrotic, and gangrenous skin and oropharyngeal lesions described in Dr Short's case 1 are classical lesions of polyarteritis nodosa, the bloating of the face from œdema (likened elsewhere to cadaveric decomposition), the inevitable visceral involvement by infarction, the leucocytosis, and the albuminuria and cylindruria are confirmatory, and the necropsy findings are indisputable As in acute systemic lupus erythematosus, these cases are a clamant indication for cortisone or corticotrophin—the value of which Dr Short has not disproved The initial daily dosage is that which controls the activity of this disordered immunity reaction and has in my experience been from 200 to 300 mg or more of cortisone or an equivalent amount of corticotrophin Control of secondary infection with antibiotics such as penicillin or aureomycin is clearly necessary, but sulphonamides are proscribed

Might I finish with a plea for consultation, in all these severely ill cases, with dermatologists, who, less blinded perhaps by the secondary infective phenomena, might possibly sooner recognise the basic condition ?

Aberdeen IAN W CALDWELL

THE B C G LESION IN *SARCOIDOSIS*

SIR,—I was most *interested* in the paper by Dr Forgacs and his colleagues (Jan 26) My findings[1] with regard to the rate of development of the B C G lesion, its characteristics, and its failure to convert the Mantoux reaction were identical to those reported by Forgacs et al in three cases of sarcoidosis so tested Further, two other examples of diseases in which a negative Mantoux reaction is common—leprosy and acne agminata (lupus miliaris disseminatus faciei)—reacted in a similar fashion

About 10% of normal individuals who are tuberculin-negative do not become tuberculin positive after B C G vaccination, and I suggested at the time that the particular constitutional peculiarity may have some bearing on the future development of sarcoidosis Now that B C G vaccination has been performed on a large scale for some years, it should be possible to institute long-term follow-up of these individuals to test the hypothesis

London, W 1 PETER BORRIE

MASSIVE THROMBOPHLEBITIS

SIR,—Mr *Catchpole (Feb 16) seems to doubt* the association of venospasm with massive thrombophlebitis In the following case, seen some years ago, there was severe venospasm

A middle aged man, who had been in bed for some [illegible] on account of a medical condition, suddenly complained of excruciating pain in the left leg On examination a short time afterwards, the leg was slightly œdematous, and markedly cyanosed up to the groin Peripheral arterial pulses were present, and the foot was covered with multiple small petechiae The most striking feature was distension of the pretibial veins, which seemed to be under almost arterial pressure At the end of half an hour, the pain, cyanosis, and venous distension disappeared completely for several hours, only to recur for a further hour or so some hours later Approximately six hours later the condition recurred for a third time, and on this occasion did not disappear, thus finally constituting the typical picture of massive thrombosis of the common or internal iliac vein

The staged evolution of this disease picture can only be explained by the occurrence of intermittent severe venospasm, though this was probably reactive to established clot formation

Leicester Royal Infirmary H J GOLDSMITH

PRESSOR AMINES IN THE URINE

SIR,—The estimation of the urinary excretion of adrenaline and noradrenaline is the most satisfactory test for the presence of a phæochromocytoma Despite the recent report by Litchfield and Peart[1] of a case in which there was no excess of pressor amines in the urine, the estimation is becoming a routine investigation in patients with severe hypertension

Whichever of the several available methods is used for the test, the laboratory results must be considered in relation to the patient's clinical state, and it must always be remembered that the diagnosis is not finally established by the laboratory, but by the physician in charge of the patient This is especially the case if a full history does not accompany the urine specimen to the laboratory

In the course of urinary pressor amine estimations[2] on nearly 2000 patients, of whom 20 proved to have a phæochromocytoma, we have come across certain well defined difficulties and feel that attention should be drawn to these

We have recently found that a hypertensive lady with asthma, who used a 2% adrenaline spray, excreted sufficient adrenaline in her urine *for the result of our assay* to suggest the presence of an adrenal tumour Subsequent tests in this patient gave normal figures, while another, *non-hypertensive,* asthmatic using an isoprenaline spray was found to have an abnormal amount of noradrenaline in her urine *Patients* should clearly not be receiving any sympathomimetic drug during the collection of urine specimens for assay

Other drugs may also interfere with the test Burn[3] has shown that the pressor-amine excretion may be greatly increased in the twenty-four hours following a phentolamine test, and we consider that samples should not be collected for at least three days after this, and (until further information is available) after any similar test

---

[1] Litchfield J W Peart, W S *Lancet* 1956 ii, 1283
[2] Moulton R Willoughby, D A *Ibid* 1955, ii, 16
[3] Burn G P *Brit med J* 1953 i 697

Forssman[4] has found a considerable increase in noradrenaline output following a coronary thrombosis. We have recently found a raised noradrenaline level (to the very high figure of 0·5 µg. per ml.) in the urine of a known hypertensive who had collapsed as a result of a cerebrovascular catastrophe from which he died a few hours after the specimen had been collected. No phæochromocytoma was found post mortem. We have also found a raised noradrenaline level in the urine of a hypertensive patient who had had a subarachnoid hæmorrhage. Repeated determinations failed to confirm the original high levels and other tests did not indicate the presence of a tumour. Single high readings always require confirmation on further specimens.

So long as such limitations are appreciated, the estimation of urinary pressor amines remains the most reliable single test for a phæochromocytoma. It is the only satisfactory method for screening large numbers of patients, but the results must always be critically assessed.

R. MOULTON
M. L. ROSENHEIM
D. A. WILLOUGHBY

THE REMUNERATION CLAIM

SIR,—Dr. Noel Alder (Feb. 9) draws attention to a recent meeting of the Brighton and Mid-Sussex Division of the British Medical Association, where it was decided to form a local committee of the British Medical Guild which would organise our withdrawal from the National Health Service, if this action should become necessary. At this meeting a number of members advocated resignation from the service if the new Minister of Health proved to be as intransigent as his predecessor. I think the attitude of these members fairly reflected the temper of the meeting as a whole; Dr. Noel Alder, however, regards resignation as "shameless blackmail" and deplores the use of "trade-union tactics".

What would Dr. Alder have us do? Continue to watch our distinguished leaders suffer indignity and discourtesy at the hands of successive Ministers, and their permanent officials, while they plead our case? I am sure he must dislike this humiliation as much as the rest of us.

Dr. Alder, and those who think like him, should remember that the majority of the profession voted against accepting the terms of service in 1948, and those who were in favour at least believed the Spens recommendations would be adhered to. By now the most ardent advocates of the N.H.S. have their doubts, while the rest of us search for a way out or hope for reform.

I am not alone in thinking that a forced withdrawal may be our salvation; our profession should now know what to do with a second chance.

Hove, Sussex. PATRICK HALL SMITH

PRESCRIBING PHENINDIONE

SIR,—The anticoagulant drug phenindione, is familiar under the trade name 'Dindevan' as scored tablets in one strength only—50 mg., from which dosage schedules in multiples of 25 mg. may be arranged. There is now a need for a weaker strength if advantage is to be taken of the more accurate stabilisation of patients by means of Owren's modified method of estimating the "one stage prothrombin time".[5]

The advantages claimed for this method of controlling anticoagulant therapy are that it is sensitive to dosage increments of 10 mg. and thus allows stabilisation of patients whose dosage requirements do not coincide with multiples of 25 mg. Trends towards overdosage are obvious and the correct dose can often be decided two to three days earlier than with the older method.

The makers (Evans Medical Supplies Ltd.) are ready to supply a 10-mg. tablet of dindevan to meet this need. With this new strength, however, difficulties for the prescriber and pharmacist may arise.

The *British Pharmacopœia 1953* (Addendum 1955) directs that "if the quantity [of phenindione] contained in a tablet is not stated, tablets containing, in each, 50 mgm. shall be supplied or dispensed." If this directive were followed, the pharmacist would supply tablets which might be five times the strength of those intended.

So that there may be no doubt as to what should be supplied, prescriptions or orders for this drug should state the precise dose in milligrammes, or the strength of the tablet required.

United Oxford Hospitals.

ROSEMARY BIGGS
W. TRILLWOOD

SOIL, FOOD, AND HEALTH

SIR,—It is a pity that in your excellent annotation of Jan. 19 you should have fallen into the usual error of criticising organic husbandry on incorrect assumptions. In fact it does not depend on making compost; nor does it depend on *not* using mineral fertilisers; nor does it involve a reduction in the intensity of production. These fallacies arise out of a failure to appreciate the principles upon which organic husbandry is based.

Under natural conditions the fertility of the soil is dependent upon the soil organisms which, by their activities, convert the minerals, which are present in most soils in unlimited quantities, into a form in which they are available to plant life. The degree of activity of the soil organisms is dependent upon their food supply, which consists of decayed and decaying organic matter, both animal and vegetable.

The principle of organic husbandry is to exploit this mechanism to the full. This is accomplished first by making good any deficiencies in the mineral content of the soil—especially lime, phosphates, and (when necessary) trace elements—and then to feed the soil organisms so that they in turn can feed the crop. This is accomplished: (1) by deep-rooting leys which, by their extensive root system, produce a large bulk of organic matter as well as bringing up the minerals from the depths of the soil; and (2) by applying as much organic matter as possible to the surface layers of the soil, chiefly by means of the grazing animal, but also by the application of previously matured dung or compost which is more immediately available as a source of food.

The value of such applications lies not in the amount of minerals that they may contain, but as a means of feeding the soil and thus ensuring the release of the minerals that it already contains. There are a number of large scale farms in this country where no soluble mineral fertilisers are used, and little if any compost, but whose yields compare favourably with the best in the country.

Inorganic husbandry on the other hand seeks to short-circuit the natural process by supplying the necessary minerals in a soluble form that is immediately available to plant life. It is based on the presumption that we know exactly what minerals, including trace minerals, any crop requires; in what form, and in what balance—and that even if we don't it doesn't much matter.

Now that it is becoming increasingly recognised how many states of ill health are basically deficiency diseases, even including some infective processes, the above assumptions appear to be at least highly questionable from the medical point of view.

Although it is true that high yields can be forced easily and fairly cheaply by the use of soluble mineral fertilisers, it is also true that the products so grown are different in their chemical composition from those grown by natural means, and especially in the structure of their proteins. Whether such differences are harmful or not is surely a matter of vital importance to the future of preventive medicine, and we should therefore give all the support we can to research work such as that which is being carried out at Haughley

UNMARRIED PARENTHOOD

SIR,—The approach shown by Dr Cordeaux's letter last week is unphysiological Young men, whether they know it or not, have to experiment to discover which of the socially acceptable patterns of eating and drinking available suit them best, the need for similar experimenting in the doubly difficult (since two people have to be satisfied) field of sex must be obvious

Every branch of medicine must carry its quota of preventable tragedies, but until the adoption societies can meet all the demands they receive for children I do not feel that that of the unmarried mother is very serious, and I would prefer to ask your readers' sympathy for couples who, because they are so well aware of the responsibilities of marriage, or perhaps cannot see a way of assuming them without jeopardising a worth-while career, defer matrimony until the late 30s Many such couples, influenced by the propaganda of moral societies, abstain from intercourse in the misplaced trust that the mature affection and respect they feel for one another must lead to satisfactory physical consummation

No serious person doubts that morality is of the highest importance to any civilised society But morality is not the same as dogma, and moral agencies that dabble with sex without submitting *their dogmata to continual* scrutiny in the light of changing circumstances and increasing knowledge must carry a large share of responsibility for the divorces, delinquencies, frustrations, and ill health that spring directly from the failures in sexual adjustment

London N W 1 J F TUTHILL

X RAYS AND LEUKÆMIA

SIR,—I should like to congratulate Dr Rabinowitch on his thoughtful letters (Dec 15 and Jan 26) and also to offer some further observations of my own

It is perhaps unfortunate that Dr Alice Stewart's preliminary communication (Sept 1) on the possible relationship between malignant disease in childhood and diagnostic X rays in pregnancy received so much publicity Many doctors and—with more excuse—patients seem to have accepted headline announcements such as "X-ray Examinations as Cause of Cancer in Children" as proof that a case has been established Much apprehension has been caused and there is evidence of a growing tendency to discard one of the most valuable diagnostic procedures in the elucidation of difficult obstetric problems Personally, I can see no grounds for such fears in Dr Stewart's article, for the following reasons

1 Only 85 of the 547 cases of leukæmia or cancer were exposed to antenatal irradiation

2 45 of the 547 controls were similarly irradiated, without any known ill effects to the fœtus It is a reasonable assumption, therefore, that at least 45 of the malignant cases received a similar harmless dose of X rays This leaves only 40 (7 3%) of the 547 cases in which leukæmia or cancer might have been caused by diagnostic irradiation

3 There is reason to doubt whether Dr Stewart's cont are acceptable It is well known that X ray examinat are much more commonly performed in the first pregna than in subsequent ones, to be strictly comparable the fore the case and control groups should have b matched for parity This point was raised by Dr Ellis a Dr Lewis (Sept 15), Dr Stewart's reply being that "th were deliberately not matched for birth rank" and that "t child population dying of leukæmia and cancer nowad *includes a disproportionately large number of* first b children and twins" But, if the control group had contai a *similar* "*disproportionately* large number of first b children and twins," we should have expected *more* than of the 547 mothers to have been X rayed during pregn —perhaps even 85—in which case Dr Stewart's argu falls completely to the ground

In my opinion, Dr Stewart has provided no convin proof of any danger to the fœtus during antenatal X r examinations I would strongly suggest, therefore, th there shall be no change in the attitude of obstetric and radiologists towards X rays in pregnancy un such time as Dr Stewart completes and publishes h investigations

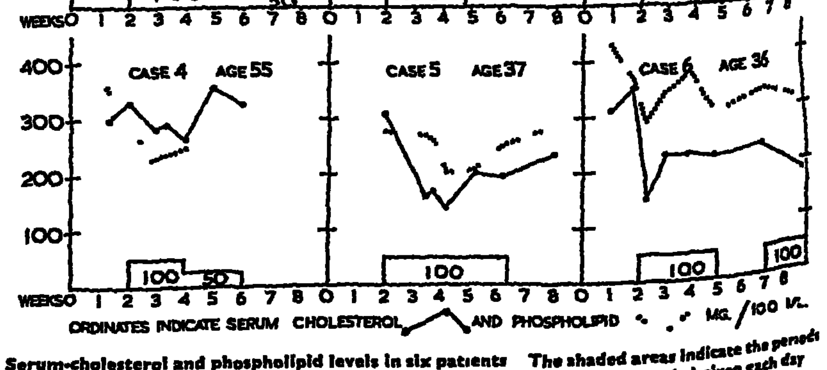
Harrogate FRANK REID

SUNFLOWER-SEED OIL AND SERUM-LIPIDS

SIR,—Bronte Stewart et al [1] reported that oral admin istration of sunflower seed oil or of a marine animal o lowers the level of cholesterol and β lipoproteins in th serum, even when a high-fat diet is taken The iodi value of the oil they used was 130-138, and its linoleic aci content 60%

We have given sunflower seed oil to six men, with occlusive vascular disease (Its iodine value was 137 5, and it contained 59 3% linoleic acid, with palmitic 5 6%, stearic 2 2%, arachidonic 0 9%, and oleic 32 0%) Al but case 4 were treated as outpatients and had been o a low-fat diet for some months previously The daily consumption of the oil (usually *100 g* in three or fou doses) and the period of administration are shown in th chart Apart from occasional diarrhœa and slight tem porary nausea there were no gastro intestinal disturb ances, and no undue difficulties in continuing the treatment

Oral administration of sunflower seed oil to this small group of patients, in whom the initial serum cholesterol



Serum-cholesterol and phospholipid levels in six patients The shaded areas indicate the periods during which sunflower-seed oil was given the figures represent the dose (g) given each day

---

1 Bronte Stewart, B Antonis, A, Eales, L Brock, J F La 1956, i, 521

EFFECT OF SUNFLOWER SEED OIL ON CHOLESTEROL AND PHOSPHOLIPID LEVELS

Case	Age	Diagnosis	Serum levels before oil treatment (mg per 100 ml)		Maximum fall achieved (mg per 100 ml)	
			Cholesterol	Phospholipid	Cholesterol	Phospholipid
1	39	Angina of effort	270–323	269–288	92	Not significant
2	33	Thromboangiitis obliterans	352–400	300–320	30	Not significant
3	48	Intermittent claudication	232–258	204–257	41	75
4	55	Coronary thrombosis	300	360	64	130
5	37	Coronary thrombosis	286–370	220–300	220	97
6	35	Coronary thrombosis	290–380	238–375	167	74

and phospholipid levels were not excessively high, produced varying responses, those of cases 2 and 3 being the least striking (see table) In the others serum-cholesterol levels fell appreciably, with a tendency to rise during treatment in case 5 When the treatment was stopped (cases 1, 2, 5, and 6) or the dose of oil was reduced (case 4), these values tended to rise again promptly

In case 4, anticoagulant therapy, which had ceased only four days before sunflower seed oil was given, may have influenced the earlier cholesterol concentrations Anticoagulants had also been given in case 5—five months previously

Other patients with much higher initial serum-cholesterol and phospholipid levels have given more encouraging results with this treatment

These results correspond with those of Bronte-Stewart et al, and seem to support their suggestion that serum-lipid levels may be materially affected by the dietary intake of unsaturated fatty acids

We wish to thank Mr A D Wilson, of Unilever Ltd, who supplied the oil, together with analytical data concerning its composition We also thank Dr Robert Gaddie, biochemist, General Hospital, Birmingham, for several of the blood analyses

RADIOACTIVE VITAMIN B_{12} IN THE DIAGNOSIS OF NEUROLOGICAL DISORDERS

SIR,—The most direct methods of confirming the diagnosis of subacute combined degeneration of the cord are those which demonstrate an inability to absorb vitamin B_{12} or a deficiency of it in the serum Dr Berlyne and his colleagues (Feb 9) describe a test of vitamin-B_{12} absorption which makes small demands on skill and labour, although it requires expensive apparatus

We think however, that there is more to be said for gastric analysis than Dr Berlyne and his colleagues say, and we would like to emphasise yet again the fallacies in conventional tests of gastric function

(1) The tube must be in the body of the stomach and not coiled near the cardia To ensure this it is best to pass the tube (once the tip is in the œsophagus) with the patient prone The final position should be checked either by a radiograph or, more easily, with a magnet tipped tube and compass [1]

(2) The secretory stimulus must be prolonged as well as powerful, so that where secretion is slow there is time for the antacid effect of saliva and other non acid secretions which the fasting stomach may contain to be overcome This requirement is not met by a single injection of histamine [2] We give, if necessary, four injections of 0 5 mg of histamine acid phosphate at intervals of twenty minutes

(3) Acidity is most adequately estimated with a pH meter If indicators have to be relied on it is probably better to use several One can then detect increases of acidity which, although not quite large enough to turn Töpfer's reagent (pH 3), suffice to show that secretion has occurred Nevertheless we have always been able, except in absolute achlorhydria where the pH remains between 6 and 8, to obtain samples acid to Töpfer's reagent, and we test each sample at the bedside with this indicator

We have used gastric sampling in this way in cases where subacute combined degeneration was suspected, and have had help from it similar to that which Dr Berlyne and his colleagues have had from their test with radioactive vitamin B_{12} In particular, we have demonstrated the ability to secrete acid in 3 patients who, as result of ordinary testing, had been described as having "histamine-fast achlorhydria"

We hope that Dr Berlyne and his colleagues will use a gastric test of the kind we describe in conjunction with their further studies, which may then not render gastric analysis "outmoded"

MANUAL ARTIFICIAL RESPIRATION IN THE SITTING POSTURE

SIR,—I was interested to read the article by Dr Henning Ruben (Jan 19) May I, however, query his statement that "during the intermittent flexion of the body the abdominal viscera press not only on the diaphragm but also on the vena cava, thus possibly helping to pump the blood towards the heart" Should this stimulation of the circulation be put forward in a manner suggesting that it is good treatment? Would it not tend to overload the right side of the heart which is already having difficulty in pumping blood round the inactive lungs? In such cases, stimulation of the circulation is usually recommended *after* breathing has recommenced

Ashby de la Zouch   A H M CAMPBELL

NEW DRUGS, OLD DANGERS

SIR,—Your leading article of Feb 9 wisely advises us to use a new drug "only when there is a clear indication for it, and when hospital trial has firmly established its superiority over its more familiar predecessors," adding that "then the occasional reaction is a risk that is justified"

By implication the drugs quoted have not passed these tests—phenylbutazone, probably because there are safer alternatives available, and chlorpromazine and meprobamate probably because the disability to be relieved often scarcely justifies the known risk But we wonder whether carbimazole has not a more established place? Like many widely used drugs unfortunately it is occasionally toxic, but probably less frequently than any available similar anti thyroid drug [1] one alternative (perchlorate) may be less toxic, but a full assessment of its risk is not yet available, and its different anti thyroid action gives a less satisfactory clinical control

Proper supervision of the use of such a drug should include provisions to ensure the early and full treatment of any toxic effects, and it is possible that some of the fatalities from carbimazole and similar drugs have occurred when these have failed—either when the carbimazole has not been stopped on the first symptoms [2] or when the infection complicating the agranulocytosis has not been controlled [3] To any patients given carbimazole we give clear instructions to stop taking the drug and report immediately if pyrexia, sore throat, or other unusual symptoms develop, and blood counts on these visits are essential, though of little help at other times Should agranulocytosis be discovered, as you say, "blood transfusion and penicillin are always advisable," but it is the antibiotics that matter and penicillin may not suffice If within 24–48 hours the patient is not improving, fuller antibiotic resources must be used Over previous years when treating agranulocytosis due to methylthiouracil, we have on occasion needed to add streptomycin or aureomycin to lower the fever and arrest the infection We trust that your gloomy statement that "if recovery is going to take place, polymorphs return to the blood within 2 to 3 days" will not suppress vigorous *pursuit of adequate antibiotic treatment in such patients,* for we have seen full recovery after the complete absence of polymorphs from the blood for over 12 days

CLINICAL PICTURE OF SICKLE-CELL DISEASE

SIR,—Your admirable leading article of Feb 16 on sickle cell disease contains statements on the proportions of different hæmoglobins in certain hæmoglobinopathies which might mislead pathologists in their investigations should they not be familiar with the subject

In sickle-cell anæmia the red cells contain 75–100% of hæmoglobin S and 0–25% of fœtal hæmoglobin—and not 0–25% of normal hæmoglobin A In sickle cell/hæmoglobin C disease the proportion of hæmoglobin S is greater than that of hæmoglobin C—and not about 50% each In sickle cell/thalassæmia the proportion of hæmoglobin S may vary from 25 to 90% or more, but it is true to say that the condition is symptomless and not a "disease" when the proportion of hæmoglobin S is below 50% In either case hæmoglobin A is frequently not "a small remainder" but may be present in a significant proportion

CHEMICAL CARCINOGENS AND THEIR SIGNIFICANCE

SIR,—We have read with great appreciation Dr J W Cook's succinct account last week of the present status of this subject and agree with his suggestion that the study of chemical carcinogens is likely to prove one of the most profitable forms of cancer research There are, however, two statements which do not take into account all the experimentally proved facts, and which, carrying the authority of Dr Cook, may give a misleading impression

The carcinogenic hydrocarbons undoubtedly act locally at the site of direct application, but to describe this as a characteristic ignores the induction of mammary cancer by cutaneous intranasal, intraperitoneal, and intragastric administration of methylcholanthrene, and of ovarian cancer by cutaneous treatment with dimethylbenzanthracene [1–4]

The idea that the mechanism by which polycyclic hydrocarbons "transform normal cells into cancer cells" is associated with their becoming firmly attached to skin proteins cannot be easily sustained in view of the finding that such protein binding may also occur with non-carcinogenic substances of related chemical structure [5 6]

BIRTHDAYS OF SPASTICS

SIR,—Our experience certainly differs from that of Dr Bevan (Feb 16) Birthdays of the last 30 childr admitted *to this hospital* with cerebral palsy w distributed as follows January–March, 14, Apri June, 3, July–September, 15, October–December, 1

Alexandra Hospital,
Luton, Bedfordshire **H B LE**

TETRAETHYL LEAD POISONING

SIR,—The case described by Dr G L Robinson in h letter last week is not really typical of tetraethyl le *poisoning because neither a marked anæmia nor punct* basophilia are characteristic of this form of lead poison and the central nervous system is always affected

Scaling of tanks which have contained leaded pe usually results in exposure to inorganic lead salts co bined with other lead compounds which are the re of the breakdown of tetraethyl lead It would seem th the brief description of this particular case is s stantially that of ordinary lead poisoning

It should also be mentioned that lead can alw found in the urine of normal people who have had specific exposure, since this metal is invariably pres in very small amounts in the atmosphere and food of a industrial community Accurate methods of analy have proved these facts

Finally I doubt very much if any case of ordinary plumbism with normal kidney function would have *typical symptoms and signs unaccompanied* by a excretion of lead in the urine in excess of normal

A MISSED FRACTURE

SIR,—Dr Hunter last week suggested that my lett of Feb 2 might be taken as "a piece of sarcasm" Although I may have rather "laid it on," what I wish to do was to draw attention once again to the difficulties confronting a junior casualty officer and to suggest that everyone should not rush to criticise him every time he made a mistake It is time that some increased form of protection was afforded to these doctors in their work or there very soon won't be any

Newcastle upon Tyne **J F STOW**

SYPHILITIC AORTIC INCOMPETENCE

SIR,—Dr J C Leonard and Dr W G Smith are to be congratulated on their excellent study of the progno and effects of treatment of syphilitic aortic incompetence (Feb 2), and few people will quarrel with their main conclusions

Nevertheless their recommendation that it is probably best to give at least one full course of arsenic or bismuth to every patient, in addition to systemic penicillin requires some comment *The figures on* which this recommendation is based are, in their own words " small that it is impossible to be certain that the resul are of definite significance This does *not* seem to be a adequate reason for reintroducing in the treatment of t condition highly toxic drugs such as the organic arsenicals Severe reactions to these drugs were common, sensitivity frequently developed, and fatalities were far from rare Patients with syphilitic aortitis are usually middle aged or elderly and, in the past, proved particularly susceptible to the ill effects of this treatment

Surely, if better results are desired in the treatment of syphilitic heart-disease, it would be more reasonable to try to obtain them by increasing the dosage of penicillin up to at least 8–10 mega units, by giving a course of intramuscular bismuth, and possibly by repeating the course of penicillin on one or more occasions

I believe most physicians who have treated such patients, and all with any extensive experience of senical therapy, consider that there is now no indication r the use of these dangerous drugs in the treatment of philis

J K OATES

ANTIMALARIALS AND RHEUMATOID ARTHRITIS

SIR,—Dr Allison and Dr Ray Bettley (Feb 9) are to congratulated on drawing our attention to chronic leg ceration in rheumatoid arthritis and suggesting that rhaps this association is not rare They show underandable caution in their interpretation of the finding of E cells in 4 of their 6 patients who otherwise would ave been regarded simply as suffering from long standing eumatoid arthritis, with rheumatoid nodules and ippling deformities to substantiate the diagnosis

Pathologists now have sufficient experience to enable em to identify L.E cells which would be acceptable as ch to their colleagues The significance of this cell is ow being freely discussed between them and clinicians, ; the cell specific to lupus erythematosus or not ? While his controversy is pursued, I must point out that patients ith rheumatoid arthritis are being crippled now linicians accept the value of chloroquine and certain ther antimalarials in disseminated lupus erythematosus urge them to try these drugs in rheumatoid arthritis have shown that they are of value in a short-term ontrolled investigation[1] and am endeavouring to stablish their long-term value, of which I am convinced n clinical grounds

ERYTHROCYTE-POTASSIUM LEVELS IN RHEUMATOID ARTHRITIS

SIR,—I was interested to read the preliminary communication by Dr Knudsen and Mr Thomas (Feb 2)

We are carrying out a similar investigation here in connection with the use of adrenal corticoids in chest disease Our method is likewise to calculate the erythrocyte potassium level from the whole blood-potassium and the hæmatocrit value, using heparinised venous blood and undertaking the estimations with as little delay as possible, although with different dilutions (1 in 500 for whole blood-potassium and 1 in 50 for plasma potassium samples) The group we have analysed so far consists of patients with pulmonary tuberculosis, who are symptom free but are receiving chemotherapy 69 estimations have been made in this group, with a mean erythrocyte potassium level of 105 m eq per litre The distribution of values around the mean fits very closely the pattern of a normal (Gaussian) curve, with a standard deviation of 5 m eq per litre We have to date found a negative correlation between the erythrocyte-potassium levels and hæmatocrit readings (r = –0 57) We are also investigating a normal control group, consisting of hospital staff and patients with chest disease who are receiving adrenal corticoids

"WINTER VOMITING DISEASE"

SIR,—I read the paper by Dr Haworth and his colleagues[2] with great interest and would like to refer to my own experience[3]

In an agricultural settlement, with a population of 1400 102 cases occurred during the three summer months of 1954, 83 of the patients were children up to 16 years of age and the age group particularly involved was the 3–6 year olds

The illness was principally characterised by sudden onset, vomiting, extremely severe headache, vertigo, meningism, temperature up to 38 5°C, absence of any other complications, and rapid recovery A lumbar puncture in a 5 year old girl with a definite Kernig's sign and absent knee jerks showed 21 cells per c mm, 28 mg protein per 100 ml, and no organisms Adults particularly complained of "pressure behind the eyes" and very severe headache Because of dizziness, which persisted for up to three days, the patients scarcely dared to turn the head A few patients had a mild relapse after six or seven days The incubation period was probably seven days

We, too, were unable to detect the causal agent In the same year cases of West Nile fever were reported in Israel Investigation was made in this direction, but with negative results

Ein Harod, Israel

A KALLNER

DISCREPANCIES IN THE ERYTHROCYTE-SEDIMENTATION TEST

SIR,—The discrepancies in the E S R test in rheumatic fever found by Dr Alexander and Mr Andrews (Feb 2) have been fully described by, among others, Enocksson et al,[1] Wilander,[2] Strom,[3] von Kaulla,[4] Nielsen,[5] and Oestner[6] I found the same phenomenon during a study of the E S R in defibrinated and undiluted blood[7]

Oestner explains its occurrence as follows

> In undiluted blood, in which the content of fibrinogen, globulin, and erythrocytes is greater than in diluted blood, particularly when the absolute values of protein are high, such large aggregates of erythrocytes are formed that these can close off completely the lumen of the sedimentation tube The sedimentation process is thus impeded, Sometimes, when an aggregate breaks loose, sedimentation can then continue, giving rise to characteristic forms in the sedimentation curve, which are not found when diluted blood is used

Naturally this phenomenon is not specific to any particular disease

Amsterdam Netherlands

A S GROEN

TREATMENT OF DISSEMINATED SCLEROSIS WITH ACTIVE AND INACTIVE DRUGS

SIR,—Seyffert[8] reported the results of treating disseminated sclerosis with phenothiazine derivatives The effect in the chronic cases was good, spastic symptoms were especially relieved I have compared the effects of a similar derivative, 'Lacumin' (*n*-methylpiperidyl 3-methylphenothiazine), with those of a placebo in 90 patients suffering from the disease

There were 33 men and 57 women, aged 24–64 years (mean 40 2) For several years they had all belonged to a special disseminated sclerosis society in Gothenburg The diagnosis was established by examinations at the neurological clinic in 54 cases The others had previously been examined at out patient departments by neurologists or in connection with the present investigation The duration of the disease varied between 2 and 30 years (mean 9 4) The degree of disability varied from slight dysfunction (slight weakness and disturbances of gait mild eye symptoms) to pronounced disturbances of gait and inability to move except in a wheel chair Most patients needed crutches All had been told about the nature of their disease Most had tried various remedies As a rule the patients kept in touch with each other, and had meetings once a month

At first lacumin was given to one group of patients After some time a rumour circulated that these tablets had unpleasant side-effects The placebo (which was called 'Lacumin P') was then introduced as a drug which had exactly the same effect as the lacumin tablets, but no side effects At the same time it was pointed out that the side effects were not serious

[6] Oestner K Ibid 1942 suppl 127
[7] Thesis Amsterdam 1953
[8] Seyffert H M Münch med Wschr 1955 97 1623

All the patients were examined neurologically before the tablets were distributed In most cases, a similar control examination was performed at the end of the treatment 12 patients could not attend in person, but sent a detailed report (by filling in a questionnaire) about their condition The dose of both drug and placebo was 1 tablet (50 mg) 4 times a day—i e , that used by Seyffert[8] The treatment lasted about 4 weeks with each type of tablet

No definite objective changes in the neurological condition could be found in any patient with either lacumin or lacumin P The most manifest result was that most of the patients had side effects with lacumin resembling those of atropine, such as tiredness, difficulty in accommodating, and dryness in the mouth In many cases we had to reduce the dose after 1–2 weeks' treatment to 1 tablet twice a day or even 1 tablet at night

Table I shows that most patients found that their condition was made worse by lacumin (general impairment of function with reduced ability to move and tiredness) Those who had improved stated that they were more agile, they slept better, their balance had improved, and they had less trouble with micturition Amelioration and exacerbation seemed independent of the severity of the disease, and of the symptoms When the lacumin was stopped, the side effects disappeared, but the amelioration or exacerbation of the disease remained for some time

TABLE I—RESULTS OF TREATMENT OF DISSEMINATED SCLEROSIS WITH LACUMIN AND PLACEBO (LACUMIN P)

Subjective effect	Lacumin	Lacumin P
Only side effects	8	
Better	13	35
Worse	47	2
No effect	15	18
Total	83	55

TABLE II—RESULTS OF TREATMENT OF 48 PATIENTS WITH DISSEMINATED SCLEROSIS WITH LACUMIN AND PLACEBO (LACUMIN P)

Subjective effect	Lacumin	Lacumin P	Total
Better	8	32	40
Worse	34	2	36
No effect	6	14	20
Total	48	48	96

$\chi^2 = 45\ 6$ $P < 0\ 001$

Lacumin P in most cases gave a feeling of improvement (increased euphoria, strength, and agility) 4 patients considered lacumin P to be indispensable Only 2 said they were worse (buzzing in the ears, increased tiredness, nausea, impaired sense of balance, increased frequency of micturition, and pricking sensation all over the body)

The results in the 48 patients who received both lacumin and the placebo are shown in table II The placebo gave a better result than lacumin, and this tendency was statistically highly significant

We must be especially critical when estimating the therapeutic effect of a drug in patients with disseminated sclerosis Spontaneous variations are common, and most of them must not be interpreted as the effect of the treatment The results of this investigation show that lacumin helped in few cases and the improvement could not be objectively verified As a rule, the side effects of the drug were pronounced, in many cases the drug had to be stopped In most cases, however, a small dose of lacumin had a favourable, slight sedative effect

The results show in a convincing way that subjective improvement can be obtained by treatment with a substance which is, pharmacologically, completely inactive This was probably because the patients strongly believed in the new treatment, and it could easily be believed that the placebo tablets were better than lacumin as they had no side effects The patients *belonged to a society and many kept in touch with each other, which may have led to suggestive influence*

Neurological Clinic,
University of Gothenburg, Sweden LARS-H BLOMBERG

Parliament

The Exchequer and the Local Authorities

ON Feb 12 Mr HENRY BROOKE, Minister of Housing and Local Government, announced that the Government had completed their review of local-government finance and outlined the conclusions which they now propose *to put before the local authorities*

The Government's proposals, he said, were designed to strengthen the local-government system In doing this it was essential to improve the financial relationship between the central Government and local authorities The ratio between Exchequer grants to local authorities and their revenue from local rates, which thirty years ago was 1 to 2 was now 6 to 5 Not only had this remarkable shift reduced the financial independence of local authorities and their degree of direct responsibility to their own ratepayers, in addition, much of the Exchequer aid was on a percentage basis towards the expenditure incurred on specific services Percentage grants, whatever their merits, carried two disadvantages First, there might be danger of excessively detailed central supervision over spending, secondly, there was no certainty from year to year what the Exchequer might be asked to contribute He was sure that the greater the independence of local authorities in the raising and the spending of their money, the better for the good health of local government The Government, after a thorough investigation, did not think it practicable to devise a satisfactory new source of local revenue Nor did they believe it right to earmark for the direct benefit of local authorities any tax that was now levied nationally Rates were in this country a well established instrument of local taxation There were still some difficulties to be overcome in the rate system, but it provided a sound basis for local finance, and no better system of local taxation has been propounded

After describing the proposed changes in the rates to be paid by industry and freight transport, Mr Brooke went on to discuss the financial relationship between the Exchequer and local authorities Here a major recasting was intended which would entail a radical revision of the structure of Exchequer grants, as well as some reduction of the grants to take account of the new rate income With a few exceptions, specific grants would be replaced by a general grant of an amount fixed in advance for a short period of years, though not necessarily at the same level for each year of the period The general grant would be distributed to all county and county borough councils in England and Wales, and to county and town councils in Scotland, by reference to objective factors (mainly of *weighted population*) which were readily ascertainable and afforded a fair and reasonable measure of the relative needs of each authority

With this change, local authorities would acquire a great increase of responsibility in determining the money to be spent on the various services, in accordance with local needs Local government would become more truly local The Government's aim was to foster and stimulate a vigorous and independent local government, and to give members of councils a greater incentive to take a lively interest in their local expenditure by placing much *more of it under their own control* Under the proposals the Government had in mind, the amount of general grant-in-aid, not tied in any way to individual services, would, at present levels of expenditure, rise from less than one-sixth to close on two-thirds of the total Exchequer grants to local authorities

A Chance to Reconsider Retirement

One of the provisions of the National Insurance Bill, the text of which was published on Feb 15, allows retirement pensioners (men under 70, women under 65) who decide to go back to work to revoke their declaration of retirement They will then be eligible to earn pension increases against their final retirement

QUESTION TIME

Onset of Surtax

Mr John Hall asked the Chancellor of the Exchequer what as his estimate of the gross salary which in 1938 would ive given a married man with two children the same purhasing value after tax as he received today from a gross lary of £2000—Mr J Enoch Powell replied For a arried man with two children a gross salary of about £620 1938–39 would have given about the same purchasing power, ter tax, as a salary of £2000 at the present time Mr Hall. oes the Minister think that a level of purchasing power of 320 is the right level at which to start surtax? Is he aware hat it is because we in this country have the highest taxation the Commonwealth on brains that so many of our able oung men and women are thinking of emigration?—Mr owell The starting level for surtax is a matter for the udget which I cannot anticipate

Prescriptions in Dermatological Clinics

Mr Philips Price asked the Minister of Health whether e was aware that in dermatological clinics throughout the ountry the average prescription requiring more than one reparation is higher than any other type of clinic, and hether, in view of the heavy burden that this puts on atients suffering from skin trouble in comparison with other ypes of cases, he would abolish making a charge of 1s on ll items in excess of a certain figure—Mr Dennis Vosper eplied My information is that there is some tendency for he average number of items for these prescriptions to be igher than the general average, but I am not satisfied that any special action is needed in addition to the existing arrangements to give assistance when it is required.

Prescription Charges

Mr H E Randall asked the Minister of Pensions and National Insurance how much of the Supplementary Estimate of the National Assistance Board is due to National Health prescription charges—Mr J A Boyd Carpenter replied About £150,000

Composite Packs

Mr Ness Edwards asked the Minister what were the composite packages now issued on one prescription—Mr Vosper replied The undermentioned sets of apparatus or dressings, each of which includes two or more articles, may be ordered as one prescription

Atomiser
Colostomy apparatus
Douche
Hypodermic syringe
Smog mask
Multiple pack dressing
Perfusion fittings
Suprapubic belt
Higginson s enema syringe
Urine sugar analysis set
Vaporiser

Dental Students

Mr M R Kimball asked the Minister how many dental students began their training in 1954, 1955, and 1956, and to what extent the number of students fell short of the future needs of the profession?—Mr Vosper replied The numbers who started the first year of their professional course at English dental schools in the academic years 1954–55, 1955–56, and 1956–57 were 381, 494, and 509 respectively the Committee on Recruitment to the Dental Profession estimated that Great Britain needed 800 new dentists each year, of which, on the basis of present distribution, the share of England and Wales would be about 700

Dental Hygienists

Mr D K Freeth asked the Minister what progress had been made with the training of ancillary dental workers.—Mr Vosper replied More than 200 dental hygienists have been trained for employment in the Forces and in the public dental service and hold my certificate of efficiency, further arrangements for the training of dental hygienists are held up until the General Dental Council have made regulations to widen the scope of their employment

Foreign Dentists

Mr N A Pannell asked the Minister when regulations would be introduced which would make it possible for those foreign dentists whose degrees or diplomas are not as yet accepted as sufficient qualification for registration to qualify by special examination—Mr Vosper replied The General Dental Council has submitted regulations to the Privy Council for approval An amendment of the regulations to accord with the views of Parliament that the examination might be mainly practical has been suggested to the council for consideration at its next meeting on March 27 and I hope it will then be possible for the regulations to be approved and introduced

Increases for War-disabled Pensioners

Mr Henry Hynd asked the Minister if he was aware that the recent award of special age allowance to war pensioners is being deducted from their National Assistance payments, and whether this is done by his authority—Mr Boyd-Carpenter replied In the case of war disability pensioners receiving National Assistance who qualify for the special age allowance, 20s of the pension will already be disregarded in the assessment of their resources for National Assistance purposes The amount by which a pension exceeds 20s is taken into account by the National Assistance Board in accordance with the National Assistance Act

Institutional Confinements

During 1955 the number of institutional confinements in England and Wales was 440,857, which was 64 75% of the total

---

Obituary

PERCIVAL HARTLEY

Kt C B E, M C, D.Sc Lond, F R.S

Sir Percival Hartley, who died in London on Feb 16 at the age of 75, had been associated with medicine from the time he joined the Lister Institute in 1906, and had made substantial contributions to the work of the profession

A Yorkshire man, he graduated with first-class honours in chemistry at the University of Leeds in 1904 From Leeds he went to the Lister Institute, on a Grocers Company research scholarship, and there obtained his introduction to biological research After two years he was appointed to the staff of the Imperial Bacteriological Laboratory at Muktesar in India, but he returned to the Lister in 1913 During the 1914–18 war he served in France with the Royal Army Medical Corps and was awarded the Military Cross

After the war Hartley obtained a post at the Wellcome Research Laboratories, where he became intensely interested in the problems of the prevention of diphtheria, a disease at that time causing about 3000 deaths a year in Britain. In 1922 he joined the staff of the National Institute for Medical Research at Hampstead, where he became the first director of the Department of Biological Standards and where he worked until he retired in 1946 It was at Hampstead that he had the opportunity of playing a major part in the prevention of diphtheria When, in 1940, the diphtheria immunisation campaign was launched in Britain, he was responsible for ensuring the purity, safety, and high quality of the prophylactic used The success of the immunisation campaign excited him intensely and he never tired of recounting the events which had led up to it, but with a genuine modesty for his own achievements

Although Hartley s work on diphtheria was perhaps his outstanding contribution to medicine, he was also actively involved, as director of the Standards Department, in many other fields, and in 1943 and 1949 we published interesting observations by him and his colleagues on the relation of such factors as shock, infection, cold, and restriction of diet to the body's capacity to produce antibody in response to an antigenic stimulus His department was responsible for preparing and maintaining many of the international biological standards and he worked untiringly in bringing these standards into effective operation on the widest possible basis He was a member of the British Pharmacopœia Commission from 1933 to 1948 and of the Medical Research Council from 1949 to 1953 After his formal retirement he worked for several years at the London School of Hygiene and Tropical Medicine and at the William Dunn School of Pathology at Oxford

Those privileged to have known Hartley will always remember him by his friendliness, courtesy, and modesty, All the patients were examined neurologically before the tablets were distributed In most cases, a similar control examination was performed at the end of the treatment 12 patients could not attend in person, but sent a detailed report (by filling in a questionnaire) about their condition The dose of both drug and placebo was 1 tablet (50 mg) 4 times a day—i e, that used by Seyffert [8] The treatment lasted about 4 weeks with each type of tablet

No definite objective changes in the neurological condition could be found in any patient with either lacumin or lacumin P The most manifest result was that most of the patients had side effects with lacumin resembling those of atropine, such as tiredness, difficulty in accommodating, and dryness in the mouth In many cases we had to reduce the dose after 1–2 weeks' treatment to 1 tablet twice a day or even 1 tablet at night

Table I shows that most patients found that their condition was made worse by lacumin (general impairment of function with reduced ability to move and tiredness) Those who had improved stated that they were more agile, they slept better, their balance had improved, and they had less trouble with micturition Amelioration and exacerbation seemed independent of the severity of the disease, and of the symptoms When the lacumin was stopped, the side effects disappeared, but the amelioration or exacerbation of the disease remained for some time

TABLE I—RESULTS OF TREATMENT OF DISSEMINATED SCLEROSIS WITH LACUMIN AND PLACEBO (LACUMIN P)

Subjective effect	Lacumin	Lacumin P
Only side effects	8	
Better	13	35
Worse	47	2
No effect	15	18
Total	83	55

TABLE II—RESULTS OF TREATMENT OF 48 PATIENTS WITH DISSEMINATED SCLEROSIS WITH LACUMIN AND PLACEBO (LACUMIN P)

Subjective effect	Lacumin	Lacumin P	Total
Better	8	32	40
Worse	34	2	36
No effect	6	14	20
Total	48	48	96

$\chi^2 = 45.6 \quad P < 0.001$

Lacumin P in most cases gave a feeling of improvement (increased euphoria, strength, and agility) 4 patients considered lacumin P to be indispensable Only 2 said they were worse (buzzing in the ears, increased tiredness, nausea, impaired sense of balance, increased frequency of micturition, and pricking sensation all over the body)

The results in the 48 patients who received both lacumin and the placebo are shown in table II The placebo gave a better result than lacumin, and this tendency was statistically highly significant

We must be especially critical when estimating the therapeutic effect of a drug in patients with disseminated sclerosis Spontaneous variations are common, and most of them must not be interpreted as the effect of the treatment The results of this investigation show that lacumin helped in few cases and the improvement could not be objectively verified As a rule, the side effects of the drug were pronounced, in many cases the drug had to be stopped In most cases, however, a small dose of lacumin had a favourable, slight sedative effect

The results show in a convincing way that subjective improvement can be obtained by treatment with a substance which is, pharmacologically, completely inactive This was probably because the patients strongly believed in the new treatment, and it could easily be believed that the placebo tablets were better than lacumin as they had no side effects The patients belonged to a society and many kept in touch w each other, which may have led to suggestive in

Parliament

The Exchequer and the Local Authorities

ON Feb 12 Mr HENRY BROOKE, Minister of Hous and Local Government, announced that the Governm had completed their review of local-government fin and outlined the conclusions which they now prop to put before the local authorities

The Government's proposals, he said, were desig strengthen the local-government system In doing it was essential to improve the financial relatio between the central Government and local author The ratio between Exchequer grants to local autho and their revenue from local rates, which thirty y ago was 1 to 2 was now 6 to 5 Not only had th remarkable shift reduced the financial independence local authorities and their degree of direct responsib to their own ratepayers, in addition, much of th Exchequer aid was on a percentage basis towards t expenditure incurred on specific services Percent grants, whatever their merits, carried two disadvanta First, there might be danger of excessively det central supervision over spending, secondly, there w no certainty from year to year what the Excheq might be asked to contribute He was sure that th greater the independence of local authorities in the r and the spending of their money, the better for the g health of local government The Government, afte thorough investigation, did not think it practicable devise a satisfactory new source of local revenue N did they believe it right to earmark for the direct bene of local authorities any tax that was now levied nati ally Rates were in this country a well establish instrument of local taxation There were still som difficulties to be overcome in the rate system, but i provided a sound basis for local finance, and no bett system of local taxation has been propounded

After describing the proposed changes in the rate t be paid by industry and freight transport, Mr Brook went on to discuss the financial relationship between th Exchequer and local authorities Here a major reconstru was intended which would entail a radical revision of the structure of Exchequer grants, as well as some reduction of the grants to take account of the new rate income With a few exceptions, specific grants wou be replaced by a general grant of an amount fixed in advance for a short period of years, though not necessarily at the same level for each year of the period The general grant would be distributed to all county and coun borough councils in England and Wales, and to county and town councils in Scotland, by reference to objective factors (mainly of weighted population) which w readily ascertainable and afforded a fair and reasonabl measure of the relative needs of each authority

With this change, local authorities would acqu a great increase of responsibility in determining the s to be spent on the various services, in accordance with local needs Local government would become more truly local The Government's aim was to foster and stimulate a vigorous and independent local government and to give members of councils a greater incentive to take a lively interest in their local expenditure by placing much more of it under their own control Under the proposal the Government had in mind, the amount of general grant-in-aid, not tied in any way to individual services, would, at present levels of expenditure, rise from less than one sixth to close on two-thirds of the total Exchequer grants to local authorities

A Chance to Reconsider Retirement

One of the provisions of the National Insurance Bill the text of which was published on Feb 15, allows retirement pensioners (men under 70, women under 65) who decide to go back to work to revoke their declarations of retirement They will then be eligible to earn pension increases against their final retirement

QUESTION TIME

Onset of Surtax

Mr John Hall asked the Chancellor of the Exchequer what s his estimate of the gross salary which in 1938 would ve given a married man with two children the same purasing value after tax as he received today from a gross ary of £2000 —Mr J Enoch Powell replied For a rried man with two children a gross salary of about £620 1938–39 would have given about the same purchasing-power, er tax, as a salary of £2000 at the present time Mr Hall es the Minister think that a level of purchasing power of 20 is the right level at which to start surtax? Is he aware at it is because we in this country have the highest taxation the Commonwealth on brains that so many of our able ung men and women are thinking of emigration?—Mr well The starting level for surtax is a matter for the dget which I cannot anticipate

Prescriptions in Dermatological Clinics

Mr Philips Price asked the Minister of Health whether was aware that in dermatological clinics throughout the untry the average prescription requiring more than one eparation is higher than any other type of clinic, and hether, in view of the heavy burden that this puts on atients suffering from skin trouble in comparison with other pes of cases, he would abolish making a charge of 1s on l items in excess of a certain figure —Mr Dennis Vosper plied My information is that there is some tendency for e average number of items for these prescriptions to be gher than the general average, but I am not satisfied that ny special action is needed in addition to the existing rangements to give assistance when it is required

Prescription Charges

Mr H E Randall asked the Minister of Pensions and ational Insurance how much of the Supplementary Estimate f the National Assistance Board is due to National Health rescription charges —Mr J A Boyd Carpenter replied bout £150,000

Composite Packs

Mr Ness Edwards asked the Minister what were the omposite packages now issued on one prescription —Mr osper replied The undermentioned sets of apparatus or ressings, each of which includes two or more articles, may e ordered as one prescription

Atomiser
Colostomy apparatus
Douche
Hypodermic syringe
Smog mask
Multiple pack dressing
Perfusion fittings
Suprapubic belt
Higginson's enema syringe
Urine sugar analysis set
Vaporiser

Dental Students

Mr M R Kimball asked the Minister how many dental tudents began their training in 1954, 1955, and 1956, and o what extent the number of students fell short of the future eeds of the profession?—Mr Vosper replied The numbers who started the first year of their professional course at English dental schools in the academic years 1954–55, 1955–56, nd 1956–57 were 381, 494, and 509 respectively, the Committee on Recruitment to the Dental Profession estimated that reat Britain needed 800 new dentists each year, of which, n the basis of present distribution, the share of England and Wales would be about 700

Dental Hygienists

Mr D K Freeth asked the Minister what progress had been made with the training of ancillary dental workers —Mr Vosper replied More than 200 dental hygienists have been trained for employment in the Forces and in the public dental service and hold my certificate of efficiency, further arrangements for the training of dental hygienists are held up until the General Dental Council have made regulations to widen the scope of their employment

Foreign Dentists

Mr N A Pannell asked the Minister when regulations would be introduced which would make it possible for those foreign dentists whose degrees or diplomas are not as yet accepted as sufficient qualification for registration to qualify by special examination —Mr Vosper replied The General Dental Council has submitted regulations to the Privy Council for approval An amendment of the regulations to accord with the views of Parliament that the examination might be mainly practical has been suggested to the council for consideration at its next meeting on March 27 and I hope it will then be possible for the regulations to be approved and introduced

Increases for War-disabled Pensioners

Mr Henry Hynd asked the Minister if he was aware that the recent award of special age allowance to war pensioners is being deducted from their National Assistance payments, and whether this is done by his authority —Mr Boyd-Carpenter replied In the case of war disability pensioners receiving National Assistance who qualify for the special age-allowance, 20s of the pension will already be disregarded in the assessment of their resources for National Assistance purposes The amount by which a pension exceeds 20s is taken into account by the National Assistance Board in accordance with the National Assistance Act

Institutional Confinements

During 1955 the number of institutional confinements in England and Wales was 440,857, which was 64 75% of the total

Obituary

PERCIVAL HARTLEY

Kt C B E, M C, D.Sc Lond, F R S

Sir Percival Hartley, who died in London on Feb 16 at the age of 75, had been associated with medicine from the time he joined the Lister Institute in 1906, and had made substantial contributions to the work of the profession

A Yorkshire man, he graduated with first-class honours in chemistry at the University of Leeds in 1904 From Leeds he went to the Lister Institute, on a Grocers Company research scholarship, and there obtained his introduction to biological research After two years he was appointed to the staff of the Imperial Bacteriological Laboratory at Muktesar in India, but he returned to the Lister in 1913 During the 1914–18 war he served in France with the Royal Army Medical Corps and was awarded the Military Cross

After the war Hartley obtained a post at the Wellcome Research Laboratories, where he became intensely interested in the problems of the prevention of diphtheria, a disease at that time causing about 3000 deaths a year in Britain In 1922 he joined the staff of the National Institute for Medical Research at Hampstead, where he became the first director of the Department of Biological Standards and where he worked until he retired in 1946 It was at Hampstead that he had the opportunity of playing a major part in the prevention of diphtheria When, in 1940, the diphtheria immunisation campaign was launched in Britain he was responsible for ensuring the purity, safety, and high quality of the prophylactic used The success of the immunisation campaign excited him intensely and he never tired of recounting the events which had led up to it but with a genuine modesty for his own achievements

Although Hartley's work on diphtheria was perhaps his outstanding contribution to medicine, he was also actively involved as director of the Standards Department, in many other fields, and in 1943 and 1949 we published interesting observations by him and his colleagues on the relation of such factors as shock, infection, cold, and restriction of diet to the body's capacity to produce antibody in response to an antigenic stimulus His department was responsible for preparing and maintaining many of the international biological standards and he worked untiringly in bringing these standards into effective operation on the widest possible basis He was a member of the British Pharmacopœia Commission from 1933 to 1948 and of the Medical Research Council from 1949 to 1953 After his formal retirement he worked for several years at the London School of Hygiene and Tropical Medicine and at the William Dunn School of Pathology at Oxford

Those privileged to have known Hartley will always remember him by his friendliness, courtesy, and modesty, as well as by his fervent devotion to his work He was a most valuable colleague, easy of approach and always ready to give what help he could

He married, in 1920, Olga Parnell, she died in 1950 He leaves two daughters

HARRY COOPER

Mr Cooper was the official reporter of the *British Medical Journal* and of many medical and scientific societies Many doctors who had never met him appreciated his skill, accuracy, and conscientiousness Those who had met him appreciated also his modesty, friendliness, and unfailing helpfulness

He was born at Boston, Lincolnshire, and learnt shorthand while he was still a child, for his father was an enthusiast and used it for all his business records Harry Cooper came to London at the beginning of the century to work with the Amalgamated Press, and his first job was to report the funeral of Queen Victoria In his spare time he did free lance work, and one of his first clients was a small camera club This contact led to his doing some reporting for the Royal Photographic Society, and this in turn led to his becoming reporter to the Röntgen Society (now the British Institute of Radiology) This appointment was his introduction to the medical profession In 1907 he attended his first annual representative meeting of the British Medical Association, in the next fifty years he missed only one

From then on much of his work was for the medical profession He was reporter for the Royal Society of Medicine, Medical Society of London, Hunterian Society Royal Medico Psychological Association, Medical Society for the Study of Venereal Diseases, Ophthalmological Society of the United Kingdom, Oxford Ophthalmological Congress, and Research Defence Society But he also reported for other scientific societies, for half a dozen friendly societies and in the law-courts The scope of his practice reflected the reputation he had won as a reliable reporter of technical matter and as the writer of workmanlike reports in lucid English

Though his health had been failing for several years, he carried on with his work The last meeting he reported was the session of the General Medical Services Committee in November He died on Feb 14 at the age of 76 He leaves a widow and a daughter

Notes and News

A BIRTHDAY TRIBUTE

On Feb 22 Sir Gordon Holmes consulting physician to the National Hospital, Queen Square, is 80 In opening the celebrations at the unveiling of his portrait on Feb 7 Dr Macdonald Critchley said that the physicians at Queen Square had felt that the reissue of some of Sir Gordon's work in a monograph[1] was not enough to mark the occasion, and Mr Harold Knight, R A, had been commissioned to paint a portrait to hang in the medical school of the National Hospital Former residents and students from all over the world had contributed The artist unhappily could not be at the unveiling, though Dr Critchley welcomed his wife, Dame Laura

Sir Francis Walshe described Sir Gordon as "the greatest teacher of clinical neurology of our time," and congratulated Mr Knight, who had "so cunningly and beautifully captured and put on canvas for us the inward spirit and the outward seeming of Gordon Holmes" Describing himself as one of Sir Gordon's oldest pupils, and a friend of nearly fifty years' standing, he paid tribute to his lessons in accurate observation and faithful and methodical recording Many distinguished neurologists in North America were proud to recall how they had striven and suffered on his ward rounds while serving as his clerks, for to suffer and to strive were among the necessary conditions for the acquisition of knowledge

Sir Francis then unveiled the portrait, and Sir Ernest Gowers, chairman of the committee of management, accepted it on behalf of the medical school

UNIVERSITIES AND PARLIAMENT

The House of Commons' Committee of Public Accounts have repeatedly declared their uneasiness at the degree of freedom allowed to the University Grants Committee in its allocation of the funds put at its disposal by Parliament The Treasury, to its credit, has long resisted additional control of the U G C,[2,3] and it has now refused its concurrence in the recommendation that papers and records relating to non recurrent grants should be open to inspection by the Auditor General[4]

The Exchequer's subvention (the Treasury points out) would fail in its object if the independence of the universities were damaged by the imposition of Government control over academic policy or academic standards This unique relation between the Government and the universities calls for financial arrangements which are also unique 'It is clear that if the Government and Parliament are to abstain from the sort of control which would normally follow from the grant of such considerable sums of public money, while at the same time being unwilling to make grants without any condition as to their allocation and use, there must be a devolution of some of the functions of Government to some body standing between the Government and the Universities, and enjoying the confidence of both" The U G C has been appointed to this rôle and the Treasury has complete confidence in the U G C 's determination and ability to discharge its functions with a full sense of responsibility both to the Government and to the universities

At the same time, the U G C and the universities recognise that the obligation to observe the strictest canons of economy and financial propriety apply with even more than ordinary force to bodies spending public money without being subject to the ordinary processes of financial control on behalf of the Government and Parliament To go some way towards the objectives of the Public Accounts Committee, the universities have agreed that in future each university and university college shall (1) formally notify its auditor of every non recurrent grant received and the purpose for which it was made and (2) ask its auditor to give a certificate in general terms to the effect that every such grant received during the accounting period was duly applied to the purpose for which it was made The Treasury expresses a hope—which will be widely shared—that the Committee of Public Accounts will be satisfied with this procedure

COST OF HOME CARE FOR THE ELDERLY

It is often said to be cheaper to keep old people in their own homes than under any form of communal care The National Corporation for the Care of Old People[1] had doubts about this, and, since no figures had apparently been published, they decided to look for a reasonable basis for estimating the actual cost of domiciliary services Details were examined in 21 cases where different services had been provided in varying amounts for old people at home The cost of each service was estimated with the help of figures given by the appropriate authorities in the area or from Ministerial statements in Parliament To make possible a direct comparison with the cost of institutional care, a figure of £2 5*s* a week representing items such as maintenance of building rent rates, fuel, provisions, and clothing, was added to the cost of the services This figure, the Corporation s report adds, may seem arbitrary but ' it can, it is thought, be justified

Estimated in this way, the cost of home care varied enormously For example, for a patient of 93 who, but for the night attendance provided, might have been in hospital, the weekly average was £9 15*s* 10*d*, for an old lady of 80, who should have been in hospital but refused to go, the cost was £8 5*s* 7*d* per week, and for 4 old ladies, described as "persons who might otherwise require part-III accommodation," the figures were £6 15*s* 6*d*, £4 7*s* £4 6*s*, and £2 14*s* The hospital costing returns for England and Wales in 1954–55 gave the weekly average inpatient cost (adjusted by the vacant bed factor) as £6 12*s* 8*d* for chronic sick hospitals and £12 6*s* for mainly general hospitals The average weekly cost of all sizes of local authority homes in the area concerned was £4 9*s* 8*d*

The governors of the Corporation do not claim that these figures finally prove the case one way or the other, but they think they do show that it is not necessarily cheaper for old people to remain at home with the help of the domiciliary services The cost and the call on available man power may be such that, on these grounds alone, institutional care would be preferable The governors hope that the publication of these figures will encourage others to make similar estimates

ATARAXICS IN NEW YORK

The Commissioner of Health of New York City asked the committee on public health of the New York Academy of Medicine to ascertain whether the present widespread use of tranquillisers was a menace to public health At present 5–10% of all prescriptions in the city are for these drugs and the proportion is increasing The committee has reported that there is no proof at present that they are a menace to public health, but it recognises the many dangers of their being taken without competent medical supervision It recommends that the sanitary code of New York city be revised to make it accord more fully with Federal rules Prescriptions for potentially harmful drugs (including tranquillisers) could then be refilled only on the order of the prescriber, which is not the case now Physicians, says the report, may be dangerously misled by the extravagant claims in the advertising of certain manufacturers, who propose far too many indications for tranquillisers and ignore their harmful effects The committee advises the city board of health to survey the advertising literature "as the first step toward bringing about improvement in it"

University of Cambridge

On Feb 9 the degree of M B was conferred on Terry Buchan and, by proxy, on A C Fernando

University of London

On Jan 30 the degree of M.D was conferred on P H Connell and J G P Hutchison

Royal College of Surgeons in Ireland

At the charter day dinner the honorary fellowship of the college was conferred on Mr T J D Lane

Bill to Restrict Sale of Alcohol in France

On Feb 13 the National Assembly voted in favour of a Bill to forbid the sale to children under 12 years old, in bars and other public places, of drinks containing more than three degrees of alcohol The Bill would also forbid the distribution or dispatch to people less than 20 years old of matter advertising any alcoholic drink

[1] The National Corporation for the Care of Old People Nuffield Lodge Regent's Park London N W 1 9th annual report of the Board of Governors, for the year ended Sept 30 1956

Queen's University, Belfast

Dr O L Wade, senior lecturer in medicine in the University of Birmingham, has been appointed to the chair of therapeutics and pharmacology in the university The duties of the post include charge of beds in the teaching hospital

Dr Wade, who is 35, was a scholar of Emanuel College Cambridge, and gained a double first in the natural sciences tripos At University College Hospital he was Acheson scholar and after qualifying in 1945 he held house appointments there and at Addenbrooke's Hospital Cambridge Later he was for a short time in the Medical Research Council pneumoconiosis unit at Cardiff Since 1951 he has been in the medical professorial unit at the Queen Elizabeth Hospital Birmingham *In 1954 he held a Rockefeller travelling* fellowship in medicine which he spent with Dr Robert Loeb and Dr Stanley Bradley at the Columbia Medical Center Dr Wade's *investigations have been into the hæmodynamics of the pulmonary* and hepatic circulations

Royal College of Surgeons of England

At a meeting of the council on Feb 14, with Sir Harry Platt, the president, in the chair, Sir Henry Dale, O M, was admitted as a member of the court of patrons The honorary medal of the college was presented to Lady Webb Johnson

Mr A L d'Abreu (Birmingham) and Mr E G Muir (King's College Hospital) were elected to the court of examiners for three years Mr A C McEachern (Adelaide) was elected a member of the court of examiners for one year Sir Harry Platt was appointed visitor to the first primary fellowship examination of the College of Physicians and Surgeons of South Africa The Hallett prize was awarded to Darrel Felix Weinman, of Ceylon The college agreed to a request from the University of Ceylon for a primary F R C S examination to be held in Colombo in *January, 1958*

A licence to practise was conferred on J R Anthony

Fellowships were granted in the Faculty of Anæsthetists to the following

J K Trotter, T R Bomonji, H M C Corfield, Peter Dinmore, Alan Thorogood, Morag J R Bastable, June E Brett, J B Montgomery J D Holdsworth D I Chisholm, Cecil Moss, R H Bolton Wendy A Clark Michael Rosen Frank Wilson Azmy Ragheb Boutros, T D W Davies W J Glover R P Holmes R T Pettigrew, H G Saunders, K B Holloway, James Moore R G Waterhouse, I E Purkis

At the Hunterian Festival dinner on Feb 14, Sir Harry Platt, president of the college, reported that the Nuffield College of Surgical Sciences now had eighty postgraduate students in residence, and it was to be officially opened by Lord Freyberg on April 5 By September, the third and final phase of reconstruction would be completed as a shell Two years ago hopes had been high, but now a halt would have to be called until the country came to realise that the college must be restored, extended, and maintained in order that it might fulfil its destiny as an international academy of surgery Sir Harry was responding to the toast of The College proposed by Sir Albert Richardson, past president of the Royal Academy, who spoke of that body's debt to John Hunter's brother, William, who in 1768 became the Academy's first professor of anatomy As a patron of the arts, William Hunter set an example which Sir *Albert Richardson enjoined* his hearers to follow His speech ranged widely and wittily, and the Archbishop *of* Canterbury, when he rose to reply for The Guests to Mr Lawrence Abel's toast, complained that the sermon had already been preached, for Sir Albert's observations had been marked by the exhortation, denunciation, and salesmanship which were the proper functions of any sermon More seriously, the Archbishop declared that doctors and others should think of themselves as concerned with persons—not with problems or cases Regarding people as problems led to the formulation of principles, principles must be related to people, for dehumanised principles led to slogans, and slogans were the work of the Devil Sir Ernest Finch, as Hunterian Orator, responded to Sir Russell Brock's toast

St *George's Hospital London*

Owing to rebuilding in the medical school, the postgraduate lectures in neurology and psychiatry have been cancelled until further notice

Institute of Dermatology, London

A semi permanent exhibition by Dr C D Calnan on cosmetic dermatitis, will be held at this institute, Lisle Street, W C 2 from March 4 to 25

Royal Society of Health

A sessional meeting of this society will be held on Thursday, Feb 28, at 10 A M in the Town Hall, West Bromwich, when the programme will include a paper by Dr J F Skone on the coloured worker

Army Appointment

Dr R Bodley Scott has been appointed honorary consultant in hæmatology to the Army at home, *in succession to the late* Sir Lionel Whitby

Council of Europe Medical Fellowships

The council has allocated 9 million French francs for medical *fellowships for 1957* This sum will provide for 100 "fellowship months" The duration of each fellowship will be at least 3 *months, and it* will cover subsistence, travel, and incidental expenses British applicants may obtain further information *from Mr W H Boucher, Ministry of Health,* Savile Row London, W 1 The closing date for applications is March 1

Royal Society of Medicine

Leverhulme Associates—The council of this society, through the Leverhulme Trust Fund, is able to appoint 100 of these associates each year who, without payment of any subscription, enjoy nearly all the privileges of fellows

Men and women are eligible provided that they are not already *fellows of the society, that they hold a full time clinical or* pre-clinical teaching or research appointment in a medical dental or veterinary department of a British university, and that their total income from academic or professional sources does not exceed £1500 p a Forms of application may be had from the deans of medical schools or from the secretary of the society, 1, Wimpole Street London, W 1 Applications may be made at any time but most vacancies are filled each year during the last week in March *For this reason it is advisable to apply between March 1 and 15*

Rockefeller Foundation Grants

During the last quarter of 1956 the Foundation distributed over $8 million Grants for medical education and public health amounted *to $1,064,709*, and for biological and medical research, $1,147,260

For the support of its field services in medical education and public health in 1957, the Foundation has appropriated *$371,625, an increase of more than $50,000 over* the amount appropriated for 1956 For the promotion of medical education *and public health throughout the world*, the Foundation maintains regional offices in Brazil, Chile, and India, and it is planned to open *one* in the Middle East this year if political conditions permit

Hunterian *Society*

At the Society's annual dinner, held in London on Feb 14 *Lord Luke confessed himself* a *new recruit to the* admirers of John Hunter He was proposing the toast of The Society and, *in preparation, he had* been *reading* the life of Hunter which the society's officers had thoughtfully provided for him It was a fascinating story if anyone had made a mark on his age it was John Hunter, *he* was a rebel, and there was a great affinity between rebels and pioneers The essence of research, Lord Luke thought, was not to be satisfied, and though research in industry was more in his line than medical research he had a feeling that in both campaigns the enemies were the same the war was being waged against waste, inefficiency, and high costs (or should it be high blood pressure ?) One of the common denominators of this work was a certain amount of vision John Hunter had had a lot of vision, and that was an attribute which Lord Luke would like to see more in evidence today In his reply Dr C D Coyle, president of the society, referred warmly to the work done on its behalf by Mr A *E Mortimer* Woolf Mr C R Rudolf, Mr R S Murley, and Dr C W Keson This year, *Dr Coyle recalled, was the 50th* anniversary of the first attendance of the Lord Mayor of London at the *society's annual dinner, and the toast of* The Lord Mayor and Corporation, dashingly proposed by Dr Macdonald Critchley, was drunk with enthusiasm Dr Critchley thanked the Lord Mayor, Colonel Sir Cullum Welch, for bringing zest and buoyancy to all his duties and for making so many gay and good natured contributions to our morale In his friendly remarks about the society, Sir Cullum said he was delighted that the Hunterian Oration was to be delivered in his home, the Mansion House A reference to the Whittington Hospital then brought him to the stone on *Highgate Hill* associated with his distinguished predecessor and he pointed out that it was wrong on three points *Dick* Whittington was Mayor (the office of Lord Mayor came later), he occupied *the civic chair four not three times, and there was no evidence* that he was ever knighted Mr Ian Robin dealt adroitly *and courteously with The Guests,* who were in the fortunate position of having Miss Rose Heilbron, Q C, to reply for them

---

Prof W W Mushin is to address the New York State Medical Society at its sesquicentennial celebrations in February In March he is to be a visiting professor of surgery (anæsthetics) in the University of California Medical Center in Los Angeles

HYPERTENSIVE STROKES

A W D LEISHMAN
MA, DM Oxfd, F R C P
CONSULTING PHYSICIAN,
UNITED SHEFFIELD HOSPITALS

IF a patient is fated to die from hypertension, the chances are that he will do so from heart failure, uræmia, cardiac infarction, or stroke Heart-failure and uræmia can usually be forecast appreciably in advance of the event, and the risk of a cardiac infarct can only be accepted philosophically as a hazard of middle life inevitably greater in a hypertensive person A stroke, the most dreaded of all these disasters, seems to offer little or no chance of prediction, and even the cause of cerebral hæmorrhage in hypertension remains to a large extent speculative

Apart from the observation of Pickering (1955) that "cerebral hæmorrhage seems to be more common in subjects with very high pressure," the patient who has the stroke seems to have received remarkably little attention, but this perhaps is not altogether surprising, for *it* is unusual for much to be known about a hypertensive patient before he has his stroke A group of hypertensive patients under regular observation since 1946 has, however, now provided an opportunity to study, at least on a modest scale, the clinical antecedents of cerebral vascular accidents

The total number of patients in this group was 234, of whom 95 (40 6%) were men and 139 (59 4%) women The present status or fate of all of these is known, and the survivors have been regularly re examined at least annually None of the patients was aged more than 60 when first examined, only 44 exceeded this age at their last examination or at the time of their death, and in every case the diastolic pressure exceeded 100 mm Hg on the occasion of their first examination No patient in this group received effective hypotensive treatment, but this is not so reprehensible as it may seem, for during much of the time covered by these observations modern drug treatment was far from established and none of the patients was considered suitable for, or was willing to undergo, surgical treatment

During the ten years covered by this study 97 (41 4%) of the 234 patients died as a consequence of hypertension,* and stroke, which accounted for 41, was easily the commonest cause of death In addition to these 28 other patients had strokes which they survived Since, however, the particular concern of this investigation was with cerebral vascular accidents, which occur at a relatively early age, this report is confined to an analysis of the 56 patients who had a stroke before the age of 60, 31 cases in which the stroke was fatal (group I) being considered separately from 25 cases where it was survived (group II) The clinical state of all these patients having been subject to regular review up to the time of their having a stroke, it was hoped that it might thus be possible to recognise among them a common clinical pattern which would be useful in future prediction of these catastrophes

It was, however, obviously desirable that the clinical features of these two groups should be further contrasted with a "control" series of patients who had survived appreciably longer without experiencing a stroke, but, to be of any value, it was clear that this must consist as far as possible of hypertensive cases of comparable severity Accordingly the control group (group III) was limited to 32 patients with diastolic pressure of 130 mm Hg or higher who had survived unscathed an average of seven years beyond the average age at which strokes developed in the first two groups Thus three groups of patients have been compared in fig 1, which records the percentage incidence in each group of clinical features which normally provide a basis for assessing the severity of hypertensive disease

The somewhat meticulous grading of diastolic pressure seems to have been justified by events, but any classification of hypertensive patients according to blood-pressure has limitations because of the notorious instability of blood-pressure, especially in the higher ranges, though this source of error can be reduced if records are made only under "basal" conditions However, readings obtained in this way appear somewhat unrealistic and are likely to bear little resemblance to blood-pressure during hours of normal activity Consequently, throughout this study, measurements have been taken under standardised conditions of rest alone, being recorded as the average pressure in both arms, in lying and standing positions Since the influence of high blood-pressure is likely to be related to "peaks" rather than "troughs" of blood-pressure, the individual blood-pressures which form the basis of comparison in fig 1 represent the highest readings of systolic and diastolic pressure among those obtained in this manner at the first and last routine examinations of each patient

In fig 1 hearts are described as enlarged when the cardio/thoracic ratio is greater than 1 2, comparison of electrocardiograms is based on the appearance of "strain pattern", and ophthalmoscopic examinations report only the incidence of papillœdema, on the one hand, and of retinal exudates and hæmorrhages, on the other, since clinical records have not allowed more accurate differentiation of the retinal appearances The remaining points of comparison scarcely need clarification, except that the criterion for "fixed specific gravity" was failure to concentrate urine after twelve hours' deprivation of fluid, and that "family history" refers to the occurrence before the age of 70 of a stroke in a parent, a brother, or a sister Apart from records of blood-pressure the comparison is invariably based on the clinical findings either at the patient's last examination before the stroke or at the most recent routine examination in the case of the patients in group III

Results

Possibly the first impression gained from this survey is that there appears to have been justification for considering fatal and non-fatal strokes as distinct clinical entities, because analyses of these two groups of patients differ appreciably However, the main purpose in presenting fig 1 is to compare each of these groups individually with the controls, because if enlightenment is forthcoming at all it should emerge from these comparisons

Comparison of Group I with Group III (fig 1)

The following five features in particular appeared with notably greater frequency among patients in group I than in the controls

	Prevalence	
	Group I	*Group III*
Diastolic pressure exceeding 149 mm Hg	68%	18%
Gross albuminuria	29%	3%
Diminished urea-clearance	30%	9%
Papillœdema	22%	0%
Urea retention	10%	0%

Figuring also more prominently in this group were higher systolic pressures, slight albuminuria, retinal exudates and hæmorrhages, abnormal electrocardiograms, and patients of normal weight, but in all these instances the difference in prevalence was considerably less impressive It is improbable also that the higher male representation (39%) in group I has any significance, for among the total of 426 hypertensive patients attending the clinic the proportion of men was very similar to this (42%), and the dearth of men eligible for the control group was entirely due to their greater mortality from hypertensive causes other than stroke Since, however, it thus appears probable that fatal strokes at this age are equally common in both sexes, the considerable preponderance of women should not affect the validity of the control group

---

* Stroke 41 uræmia 29 congestive failure 13 cardiac infarction 12 ruptured aorta 2

Although these figures unquestionably support the view *that there is an important association between very high blood-pressure and the development of a fatal cerebral vascular accident* and, in particular, have suggested that diastolic pressure of 150 mm Hg is in this respect a critical level, it is equally plain that this is not the exclusive influence, for a third of the patients have blood-pressure consistently below this level Searching therefore for other sign posts, we naturally notice the frequent appearance in these cases of signs of severe renal damage, a category which does not include loss of renal concentrating power (This is not unexpected, for this particular measure of renal impairment appears to have little prognostic importance in hypertensive disease) *It therefore seemed desirable to explore the possibility* that renal damage might be an influential factor in the absence of excessively high blood-pressure by considering first the individual renal status of the 10 patients with diastolic pressures below 150 mm Hg who died from strokes (table I)

TABLE I—RENAL STATUS OF 10 PATIENTS WITH DIASTOLIC PRESSURES LESS THAN 150 MM HG WHO DIED FROM STROKES

Case no	Diastolic pressure (mm Hg)	Albumin	Blood urea	Urea clearance	Remarks
1	149	+	Normal	Normal	
2	146	+	Normal	Normal	
3	144	+	Normal	Normal	
4	140	++	88 mg per 100 ml	25 %	
5	139	++	Normal	40 %	
6	132	+	Normal	Normal	Recurrent heart failure
7	130	–	Normal	Normal	Survived previous stroke
8	128	++	60 mg per 100 ml	30 %	
9	122	–	Normal	Normal	Survived previous stroke
10	120	–	Normal	Normal	Survived previous stroke

From the table it will be seen first that 3 patients (cases 7, 9, and 10), who were exceptional in showing the features of mild and benign hypertension, had each survived a previous stroke It seems, however, much more likely that, in these circumstances, the fatal stroke was determined by local cerebral vascular changes following infarction than that it was an expression of advanced general vascular disease If this view is *accepted, these cases should clearly constitute a category* of their own Of the remainder, cases 4, 5, and 8 were undoubtedly in renal failure when they succumbed to strokes, and the first 3 patients, each of whom retained fair renal function, showed, on the other hand, a degree of hypertension only slightly less severe than the level which has been judged rather arbitrarily to be critical. Thus there remains only 1 patient (case 6) who fails altogether to be accounted for in terms of particularly high blood-pressure or serious renal involvement There is, however, a strong suspicion that, in his case, the fatal stroke was due to massive cerebral infarction rather than to cerebral hæmorrhage, since for several years he had been an invalid with recurring attacks of hypertensive heart failure

Nevertheless, before any weight can be attached to this concept, it must clearly be tested also in relation to the control group, for, if it were found that an appreciable proportion of these patients, who, despite very high levels of blood pressure, escaped strokes also showed signs of substantial renal damage, this association would cease to have any significance However, in this respect the patients in the control group (table III) have provided a satisfying contrast, because only 1 of the 11 cases with the highest diastolic pressure in the group showed at most a noticeable degree of albuminuria Since this particular patient died at the age of 61 from cardiac infarction, one may perhaps speculate about the fate which otherwise might have overtaken him

There does therefore appear to be considerable support for the belief that signs of renal damage are second in importance only to very high blood pressure in distinguishing the hyper-

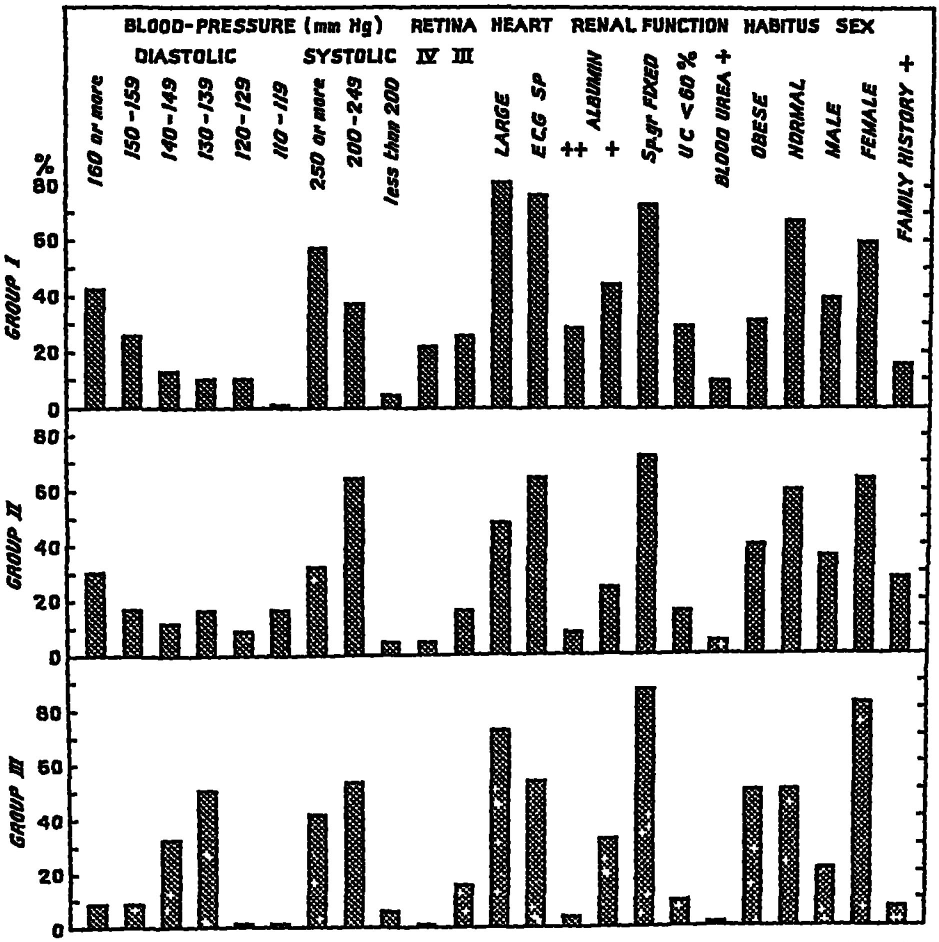

Fig 1—Analysis of clinical findings in hypertensive patients group I, fatal strokes in 31 patients (av age 50½) group II 25 patients (av age 52) who survived strokes, group III, 32 (av age 59) who had no strokes U C., urea-clearance

ensive patient who is in particular hazard of a fatal cerebral vascular accident

Apart, however, from papillœdema being seen only in patients destined to die from stroke, comparison of these two groups has revealed no other distinguishing feature, and it is important to note that, in agreement with the observations of Soloff and Bello (1948), the development of retinopathy has not appeared to have particularly sinister implications

Therefore I suggest that it is reasonable to conclude from this clinical study that (1) a fatal stroke is likely in any patient with exceptionally high blood-pressure (i e, diastolic pressure which consistently exceeds 150 mm Hg), (2) a fatal stroke may also occur when blood-pressure is somewhat lower than this if there is severe renal damage (i e, an appreciable degree of albuminuria with or without decreased urea-clearance or urea retention), and (3) there is risk of a fatal stroke at any level of blood-pressure when a patient has previously survived a stroke

TABLE II—RENAL STATUS OF 11 PATIENTS WITH DIASTOLIC PRESSURE IN EXCESS OF 140 MM HG WHO ESCAPED STROKES

Case no	Diastolic pressure (mm Hg)	Albumin	Blood urea	Urea-clearance
1	165	–	Normal	Normal
2	160	±	Normal	Normal
3	160	–	Normal	Normal
4	156	–	Normal	Normal
5	156	–	Normal	Normal
6	150	–	Normal	Normal
7	148	+	Normal	Normal
8	145	–	Normal	Normal
9	145	–	Normal	Normal
10	144	–	Normal	Normal
11	142	–	Normal	Normal

Comparison of Group II with Group III (fig 1)

In contrast to the previous comparison there appears to have been remarkably little difference in the clinical character of these two groups of patients The incidence of severe diastolic pressure (150 mm Hg or higher) was again notably higher in group II (46% compared with 18%), but no real significance can be attached to this, because the remainder of the cases in this group were evenly distributed throughout the lower ranges of blood pressure and a quarter of these patients had a diastolic pressure lower than that of any of the controls Since the highest grades of systolic pressure also were more prevalent among the controls, it must be concluded that the occurrence of this type of stroke is uninfluenced by blood-pressure

Signs of renal damage were no more evident in group II than among the controls, nor at any other point of clinical comparison was there any real difference between these groups However, patients who subsequently had a stroke provided a family history of such occurrences four times more often than did those who had so far escaped

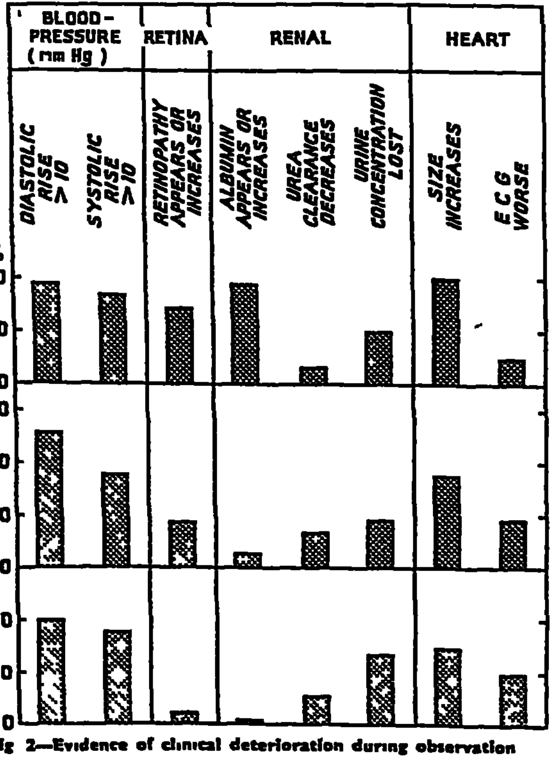

Fig 2—Evidence of clinical deterioration during observation

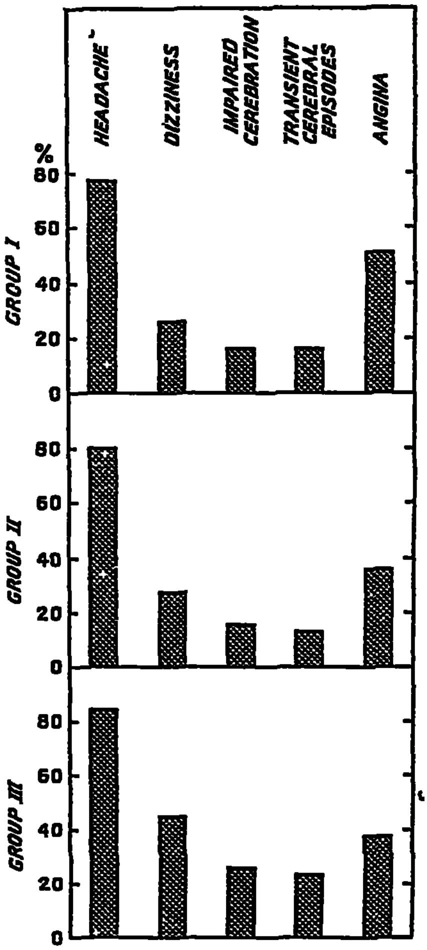

Fig 3—Comparison of symptoms

Thus the hypertensive patient destined for a stroke of this character appears to carry no special mark of identity, and it must be assumed that, apart from the undoubted influence of a family propensity, the risk of this is one that is evenly shared

The possibility that patients who have strokes may have an especially progressive form of hypertensive disease was also considered In fig 2 the three groups of patients have been further compared as regards rise of blood-pressure and other signs of clinical deterioration during observation This comparison, however, is inevitably of rather limited value because the frequency with which adverse features were recorded as appearing during observation was influenced by their previous prevalence in that group Also in this instance the number of patients in the first two groups was slightly smaller than usual owing to lack of opportunity to re-examine every patient before the stroke Nevertheless, in view of the emphasis earlier placed on this association, it is of some interest to see that patients destined to die from strokes were the only ones to show a tendency to progressive albuminuria Retinal hæmorrhages and exudates developed rather more frequently among the patients in groups I and II, but increase in blood-pressure seemed to be uniformly distributed and in all other respects the behaviour of the three groups differed very little

Finally, the incidence of certain symptoms, particularly those which may be ascribed to disturbances of cerebral circulation, is recorded in fig 3 The remarkable similarity of the three groups in this respect makes it clear, however, that such symptoms are no guide to future cerebral disaster In particular, the transient cerebral episode or "little stroke" so commonly regarded as sinister has occurred no more frequently among patients destined for strokes than among the remainder Although the nature of these attacks continues to be debated, the evidence here seems scarcely to support Pickering's (1948) contention that arterial thrombosis rather than spasm is invariably their basis

Discussion

It can be assumed that thrombosis developing in an atherosclerotic cerebral artery accounts, if not for all, at least for most strokes which have not proved fatal It is therefore no surprise that these occurrences have appeared to be uninfluenced by the severity or character of the hypertensive disease, nor is the conclusion unexpected that it is no easier to predict the development of thrombosis in a cerebral artery than its occurrence in a coronary or peripheral limb artery

Where fatal strokes are concerned, however, clinical analysis has proved more helpful, and the characteristics which appear to distinguish this group of hypertensive patients from the remainder were sufficiently prevalent to suggest that some pathological condition other than atherosclerosis may be involved here

As the constant use of the non-committal term "fatal stroke" will have suggested, the cause of these strokes unfortunately can only be inferred, because necropsy appears only to have been done in 3 cases, in each of which intracerebral hæmorrhage was found Nevertheless, except in 2 cases described as "cerebral thrombosis" and 2 further cases where this information was unobtainable, the cause of death was in every case certified by the patient's doctor as "cerebral hæmorrhage," and from the almost invariable description of rapid progressive coma there is little reason to doubt the accuracy of the certification The great majority of such patients appear to have survived only a few hours, in no case longer than twenty-four hours, thus following closely the course reported by Rose (1948) in his account of over 200 proved cases of cerebral hæmorrhage

Both subarachnoid hæmorrhage and massive cerebral infarction may be mistaken for intracerebral hæmorrhage Nevertheless, on the evidence available, it seems fair to conclude that, for practical purposes, the term "fatal stroke" can here be regarded as virtually synonymous with death from intracerebral hæmorrhage

The exact mechanism of hypertensive cerebral hæmorrhage is still largely conjectural, since objective studies have invariably been defeated by the extent of the accompanying brain damage Apart from Scheinker (1945), who suggested that bleeding might originate in cerebral veins which had become thin-walled from long-standing congestion, it has been generally assumed that the hæmorrhage is arterial, but further than this lies difficulty, for the pathological changes of arteriosclerosis lend themselves more convincingly to explanations of thrombosis than of hæmorrhage

This difficulty at least was avoided by Globus and Epstein (1953), who suggested that artery walls might become weakened in areas of ischæmic cerebral softening through lack of supporting brain substance, but it is nevertheless in terms of arteriosclerosis that an explanation of the hæmorrhage has usually been sought Eros (1951), for example, drew attention to an essentially degenerative and therefore potentially vulnerable form of arteriosclerotic change affecting cerebral arteries which constitutionally had a hypoplastic elastica Russell (1954), on the other hand, considers that the replacement of medial muscle by fibrous tissue, which she finds a characteristic of arteriosclerotic perforating cerebral arteries, adequately explains the prevalence of capsular hæmorrhages in benign hypertension

Earlier in this review it was suggested that, in a few cases where hypertension appeared surprisingly mild and benign, cerebral hæmorrhage was probably a sequel to previous cerebral thrombosis This sequence of events may logically be related to the development of arteriolar necrosis, which is not uncommonly seen in the marginal area of a cerebral infarct (Pickering 1955) In older hypertensives (excluded from this analysis) cerebral hæmorrhage has often appeared to develop upon this background, but below the age of 60 this has been exceptional, and the two features which consistently have distinguished these cases have been very high diastolic pressure (exceeding 150 mm Hg) and rather lower pressure associated with signs of renal damage, both of these features being characteristic of the "accelerated" form of hypertensive disease (The term "malignant" hypertension is traditionally reserved for such cases when papillœdema is also present)

Only 2 of the 31 patients with cerebral hæmorrhage who provide the basis for this discussion were considered likely to have had primary renal disease, and, apart from 5 patients in whom hypertension followed pregnancy toxæmia, the remainder were all regarded as having primary hypertension Thus, with few exceptions, any renal changes present were likely to be the consequence rather than the cause of the hypertension

Castleman (1951), from renal biopsy during lumbodorsal sympathectomy, established that the degree of impairment of renal function shown by a hypertensive patient was fairly closely related to the grade of arterial change found in the kidneys, and that the latter bore an even closer relationship to the height of the diastolic pressure

In a small but similar study of biopsy material from hypertensive cases of rather exceptional severity Heptinstall (1954) confirmed these findings Of especial interest for this discussion is his observation that fibrinoid necrosis of renal arterioles seemed to appear with increasing frequency as the diastolic pressure exceeded 150 mm Hg Although it is not to be expected that in every case arteries will show a precisely similar reaction to a certain level of blood pressure, the identity of this figure with the blood pressure level clinically considered particularly critical in the development of cerebral hæmorrhage seems more than a coincidence Inevitably this prompts the suggestion that fibrinoid necrosis in cerebral arterioles offers the most likely explanation for most cases of cerebral hæmorrhage in hypertensive patients, at least before the age of 60

If this explanation is correct—on a pathological basis it has been accepted by Russell (1954) as explaining the prevalence of pontine and brain stem hæmorrhages in malignant hypertension—it is likely to be of more than academic interest

It is generally believed that, unlike any other form of degenerative arterial disease, fibrinoid necrosis is a direct result of excessively high arterial blood pressure Byrom (1954) has offered the attractive theory that necrosis is a consequence of local anoxæmia of the arteriolar wall when spasm is provoked by the stimulus of high intra-arteriolar pressure, the summated effect of innumerable foci of reflex arteriolar spasm producing the characteristic pattern of accelerated or malignant hypertension

It is, however now firmly established that the malignant form of hypertension is at least potentially reversible by measures which successfully, though intermittently, lower the diastolic pressure to "safe" level By implication this also suggests that arteriolar necrosis is reversible and even more certainly is preventable Thus with increasing awareness of the absolute necessity of reducing blood pressure which approaches the critical level before irreparable kidney damage renders the impracticable, and with anticipated improvements in the drugs which will achieve this, it does not seem too much to expect that, in the future, this particular form of cerebral vascular hazard may be largely eliminated. There is indeed already a distinct impression that cerebral hæmorrhage uncommonly causes the death of a hypertensive patient who has been treated even with partial success by either sympathectomy or ganglion-blocking drugs.

Summary

A group of 234 hypertensive patients under observation for ten years provided an opportunity for studying the clinical background of cerebral vascular accidents.

During this time 97 patients died as a *consequence of* hypertension, and stroke, which accounted for 41 cases was the commonest cause of death.

The present review is concerned only with strokes which occurred before the age of 60 and is based on the study of 31 cases in which the stroke was fatal and 25 cases where it was survived. No necropsies were done, but there is reason to believe that, with very few exceptions, the fatal strokes were due to intracerebral hæmorrhage, and the non-fatal strokes mostly to cerebral thrombosis.

Since the clinical status of every patient had been fully assessed before the stroke, it was hoped that study of these cases might offer some guidance in predicting these catastrophes.

From comparison of the clinical characteristics of these cases with those of a control group of hypertensive patients who have remained free from strokes, it appears that cerebral hæmorrhage is liable to occur in any case where the diastolic pressure is excessively high (150 mm. Hg or higher) but is also likely when blood-pressure rather lower than this is accompanied by signs of severe renal damage.

Cerebral hæmorrhage, which occasionally develops as a late sequel to cerebral infarction, appears to be uninfluenced by either the severity or the character of the hypertensive condition and cannot therefore be foreseen.

The study failed to reveal any special features by which a patient destined to develop cerebral thrombosis may be identified in advance.

Cerebral symptoms were equally prevalent in the three groups of hypertensive patients studied and thus gave no indication of prognosis.

Cerebral hæmorrhage due to hypertension is not easily explained in terms of atherosclerosis, and the clinical character of the cases studied suggests that fibrinoid necrosis is likely to be mainly responsible for cerebral hæmorrhage before the age of 60.

Since fibrinoid necrosis is potentially a reversible condition and almost certainly preventable timely and effective hypotensive treatment should substantially reduce its incidence.

"Freud came upon a world that was naively sober and earnest. Truth, it held, was truth and fact—fact. Relationships were patent, or were to be made so. Reality was reality and neither ever was nor ever could be anything else. Into this all too cock certain world Freud threw the bombshell of symbolism. Reality, he asserted, stood not monolithically by itself, but in a series of relatednesses, and was in effect but the latest symbolic representation of that relatedness. Dreams spoke in symbols but so also do we, waking, for words have meaning and representations far above and behind their explicit conveyance."—Dr. I. GALDSTON, *Bull. N.Y. Acad. Med.* 1956, 32, 908.

PAGET'S DISEASE OF BONE ASSOCIATED WITH HASHIMOTO'S STRUMA LYMPHOMATOSA

A CLUE TO THE PATHOGENESIS OF PAGET'S DISEASE *

R. W. LUXTON
M.D., B.Sc. Manc., F.R.C.P.
CONSULTANT PHYSICIAN, CRUMPSALL HOSPITAL AND THE CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE, MANCHESTER

THIS paper describes the concomitance of Paget's disease of bone with Hashimoto's struma lymphomatosa in a group of patients. The association appears to be frequent enough to warrant a wider clinical and radiological study of both disorders and, if confirmed, may provide a clue to the ætiology of Paget's disease. In the present series of 35 patients with Hashimoto's disease, histological examination *of the thyroid gland was made* in 32. Of the 3 cases not so examined, 2 showed hypothyroidism, a firm goitre, and grossly abnormal serum-flocculation reactions (Luxton and Cooke 1956), and 1 had hypothyroidism with a firm goitre. Of the 35 patients with struma lymphomatosa, clinical Paget's disease (confirmed radiologically) was present in 3, and Paget's disease was discovered radiologically in 4 others. The thyroid gland was examined histologically in all the patients with Paget's disease: all showed the features typical of Hashimoto's disease.

Case-reports

Case 1.—A woman, aged 42, presented as a case of Graves's disease and was treated for four months with average doses of methyl thiouracil. The goitre became very hard and thyroid biopsy showed Hashimoto's disease (Dr. J. Davson). An X ray *of the pelvis revealed Paget's disease of bone (Dr. J. B.* Fawcitt). Serum flocculation tests, at first grossly abnormal, returned to normal twenty-three months after the start of treatment with dried thyroid gland. The serum alkaline-phosphatase, initially normal, has gradually increased to 25 King-Armstrong units per 100 ml.

Case 2.—A euthyroid woman, aged 42, presented with a large goitre of fairly soft consistence and apparently recent in origin. Paget's disease had been discovered in her right tibia five years before (Dr. J. Blair Hartley). The serum alkaline phosphatase was normal but serum flocculation tests were abnormal. The thyroid histology was that of definite but early Hashimoto's disease (Dr. Davson).

Case 3.—A woman, aged 68, had radical mastectomy for scirrhous carcinoma in 1949. In a routine follow-up chest X ray in January, 1950, the radiologist (Dr. Blair Hartley) noted Paget's disease of the right clavicle. A hard goitre was first noticed in November, 1954, its microscopic picture being that of 'lymphadenoid goitre' (Dr. Helen Russell). Radiologically the right clavicle showed no alteration during a period of five years and nine months. The patient had not had endocrine treatment for secondary carcinomatosis and there is no reasonable doubt about the diagnosis of Paget's disease.

Case 4.—A woman, aged 78, had a goitre of twelve months' duration which clinically appeared to be malignant, but which, on microscopy, showed Hashimoto's disease (Dr. Russell). Clinically there were no bone lesions, but X rays showed well-marked Paget's disease in pelvis and skull (Dr. Fawcitt). Abnormalities were present in the serum proteins, shown by electrophoresis and flocculation tests.

Case 5.—A woman, aged 55, first noticed a goitre in 1946 which was removed nine months later, its histology being typical of Hashimoto's disease (Dr. Russell). In 1955 clinical examination showed mild hypothyroidism and Paget's disease of the right tibia. The serum flocculation tests were negative. Radiologically Paget's disease was found in other bones (Dr. Fawcitt) and the diagnosis was confirmed by bone biopsy (Dr. Davson).

Case 6.—A woman, aged 69, had a hemithyroidectomy for a goitre which histologically showed Hashimoto's disease (Dr. Russell). Subsequently she was treated with dried thyroid gland Five years later the patient was euthyroid and the serum flocculation tests and serum protein electrophoretic pattern were normal Radiographs of the skull showed advanced Paget's disease (Dr Blair Hartley)

Case 7 —A woman, aged 48, had a small firm diffuse goitre, hypothyroidism, and abnormal flocculation tests Histologically, the goitre showed Hashimoto's disease (Dr Dawson) For the previous four years she had had clinical and radiological signs of what was thought to be polyostotic fibrous dysplasia affecting the left tibia, right great trochanter, and one metacarpal A second biopsy of the tibia revealed histologically that the bone lesion was, undoubtedly, Paget's disease (Dr Dawson)

Biochemical Features

In 5 of the 7 cases existing plasma-protein disturbance was revealed by abnormal serum flocculation tests or by serum-electrophoresis (Similar changes in serum-proteins had probably been present in the remaining 2 patients before treatment of the thyroid disorder, the one by partial thyroidectomy and the other by dried thyroid gland [Luxton and Cooke 1956, Roitt et al 1956]) The serum-alkaline phosphatase was within the normal range in 1 case, slightly raised (11–15 K -A units per 100 ml) in 2 cases, and persistently high in 4 cases Serum-calcium and inorganic phosphate levels were normal in the 6 cases examined

Discussion

Prevalence of Paget's Disease

The prevalence of Paget's disease in the general population may be assessed by necropsy studies and by radiological field surveys Schmorl (1932), performing 4614 necropsies on unselected persons aged over 40, found 138 with Paget's disease—a rate of 3% A recent necropsy study, comparable in its method, was made by Collins (1956) who examined in detail the skeleton of 650 unselected persons aged over 40 who died in general hospitals in Leeds and Sheffield Paget's disease was found in 24 of these cases—a rate of 3 7% Collins states that " this study was mainly concerned with the recognition of minor, localised or early lesions " and " regeneration of bone in Paget's disease always leads to an abnormal trabecular pattern, as easily recognised by the pathologist in the sawn bone as by the radiologist in the living skeleton " He observes that only a third of all cases of Paget's disease are diagnosable clinically, and that the disease is commoner in men than in women, probably in the proportion of four men to three women The prevalence figures are greatly influenced by age Collins divided his cases into 15-year groups and found Paget's disease in 1 8% of persons aged between 40 and 54 years, 3 6% between 55 and 69 years, 5% between 70 and 84 years, and 9 1% between 85 and 94 years

Paget's disease of bone is a fairly common incidental finding in radiological examinations To obtain accurate figures of its incidence, radiological surveys of the general population would need to cover the whole skeleton of each individual, for the disease may be localised to a single bone or part of one bone So far as I can ascertain, no extensive field survey of this nature has been made However, Kellgren and Lawrence (personal communication) in a study in Leigh, Lancashire, made radiological examinations of 173 unselected men in the decade 55–64 years and found 8 cases of Paget's disease ($4^1/_2$%), and of 208 women in the same age group of whom 1 showed Paget's disease ($^1/_2$%)—an over all incidence in both sexes of 2 4% The X-ray examination in each person was limited to the cervical spine, lumbar spine, pelvis, knees, hands, feet, and lateral aspect of the skull (partial) In all such studies, the criteria for making a radiological or histological diagnosis must vary slightly from one examiner to another and the factor of " observer error " must always be remembered

It is probable that the prevalence-rate of Paget's disease found by Schmorl and by Collins is reasonably accurate For assessing the presence of Paget's disease Collins's method of examination of the skeleton would seem comparable in accuracy with the limited radiological bone survey made in the patients with struma lymphomatosa Lacking precise radiological studies of the incidence of Paget's disease in the general population, I have therefore taken Collins's figures as a basis The rising prevalence of Paget's disease with increasing age is, of course, important statistically

TABLE I—DISTRIBUTION IN AGE GROUPS OF PAGET'S DISEASE AND HASHIMOTO'S DISEASE

—	Age group (years)		
	40–54	55–69	70–84
Collins's figure of prevalence of Paget's disease in the general population	1 8%	3 6%	5 0%
No of cases of Hashimoto's disease	17	14	4
No of cases of Hashimoto's disease with Paget's disease associated	3	2	2

Statistical Evaluation of Present Group of Patients

Table I shows the numbers of cases of Hashimoto's disease and of Paget's disease in the different age groups, alongside Collins's estimation of the incidence of Paget's disease in the general population Statistically the following may be deduced

1 The higher proportion of patients with Paget's disease in the whole group of 35 patients with Hashimoto's disease is statistically highly significant (P=0 0004 when tested by χ^2 with Yates's correction)

2 Although the actual number of cases of Paget's disease is small and breakdown into age-groups makes the individual statistical values less significant, tests on this basis give the following results

40–54 age group		0 006< P <0 005
55–69	„ „	P = 0 2
70–84	„ „	P = 0 01

In calculating figures for the purpose of applying statistical tests of significance, corrections have been incorporated to allow for two features which would otherwise introduce bias

(*a*) All the patients with Paget's disease in this series are women In the 1951 census population of North West England, which has been used for providing denominators, 55% in the age-group 40–84 are women, whilst in the individual age-groups enumerated above, the proportions of women are 52%, 57%, and 61% respectively

TABLE II—TIME RELATIONS BETWEEN PAGET'S DISEASE AND GOITRE

Case	Age (years) when Paget's disease first diagnosed	Time relations between diagnosis of Paget's disease and discovery of goitre	Thyroid activity before thyroid operation
1	43	Goitre 18 months before Paget's disease	Hypothyroid
2	37	Paget's disease 5 years before goitre	Euthyroid
3	69	Paget's disease 58 months before goitre	„
4	79	Goitre 18 months before Paget's disease	„
5	64	Goitre 9 years before Paget's disease	„
6	74	Goitre 5 years before Paget's disease	„
7	45	Paget's disease 46 months before goitre	Hypothyroid

(b) The prevalence of Paget's disease in the general population is in the ratio of 4 men to 3 women

Relationship between Hashimoto's Disease and Paget's Disease

Hyperthyroidism and hypothyroidism do not appear to be factors in the genesis of Paget's disease Of the patients with Paget's disease in this series, 1 was originally hyperthyroid, 1 euthyroid, and 1 hypothyroid (Preoperative observations on the state of thyroid activity were inadequate in 4 patients, neoplastic goitre being suspected)

There are three main ways in which an association between struma lymphomatosa and Paget's disease could arise struma lymphomatosa may predispose to Paget's disease, Paget's disease may predispose to struma lymphomatosa, or there could be a predisposing factor common to both diseases Table II shows the time relations between the discovery of Paget's disease and the first observation of the goitre in this group of patients It must be emphasised that in a slowly evolving disease such as Paget's, the actual time of onset is hard to assess even in terms of years A similar comment applies to struma lymphomatosa, for not only may the disease antedate the goitre, but the goitre may long remain undiscovered Table II indicates that in 4 cases an observed goitre preceded the discovery of Paget's disease by periods up to nine years, and in 3 cases known Paget's disease preceded discovery of the goitre by periods up to five years For what these figures are worth, they do not support the suggestion that either disease predisposes to the other

Summary

Of 35 patients with Hashimoto's struma lymphomatosa, 3 patients showed clinical signs of Paget's disease of bone A radiological bone survey of the 35 patients, limited in most cases to skull, lumbar spine, pelvis and upper femora, and one tibia, revealed that 7 out of the 35 patients had Paget's disease The diagnosis was confirmed by bone biopsy in 2 patients

Accurate assessment of the prevalence of Paget's disease in the general population has been attempted by others from careful necropsy examination on large series of unselected persons, and to a lesser extent, by radiological field surveys It is considered that such necropsy studies give figures of incidence of Paget's disease in the general population comparable in accuracy with the limited radiological bone survey made in the 35 cases of struma lymphomatosa

Statistical analysis shows that the prevalence rate of Paget's disease in this series of patients with struma lymphomatosa is highly significant

The pathogenesis of Paget's disease seems to be unrelated to hyperthyroidism or to hypothyroidism

The evidence available suggests that Paget's disease does not predispose to Hashimoto's disease, nor does Hashimoto's disease predispose to Paget's disease There may be some predisposing factor common to both disorders

I am indebted to several pathologists and their staffs—to Dr Helen Russell of the Christie Hospital and Holt Radium Institute, to Dr James Davson and Mr H V Street of Crumpsall Hospital, and to Dr Lois Stent and Mr David Moss of Withington Hospital The radiological bone surveys were made by Dr J Blair Hartley (at the Christie Hospital) and Dr J B Fawcitt and Dr J Cowen (at Crumpsall Hospital) Medical and surgical colleagues at Crumpsall Hospital and the Christie Hospital and Holt Radium Institute have been most helpful For expert statistical help I thank Miss Marion H Russell of the Christie Hospital and Holt Radium Institute Prof J H Kellgren and Dr J S Lawrence kindly allowed me to quote their unpublished field studies I am especially grateful to Professor Kellgren and to Prof S L Baker for their interest and advice

A METHOD OF HYPOTHERMIA FOR OPEN HEART SURGERY

B A SELLICK
M B Lond , F F A R C S
CONSULTANT ANÆSTHETIST, MIDDLESEX HOSPITAL, LONDON, AND HAREFIELD HOSPITAL, MIDDLESEX

THE value of hypothermia during open heart surgery is now well recognised The pioneer work of Bigelow in Toronto has paved the way for the use of hypothermic techniques in both cardiovascular surgery and neuro surgery He showed (Bigelow et al 1950a, b, and c) that the reduction in oxygen consumption that accompanies a fall in body temperature would permit the safe interruption of circulation to vital tissues for far longer than at normal temperatures Recent reports (Stone et al 1956) show that oxygen consumption in the human brain is reduced by two thirds at 30°C and by three quarters at 28°C A reduction of body-temperature to these levels can be expected to give an operating-time of ten minutes within the open heart without cerebral damage

Two main methods of inducing hypothermia are currently in use—extracorporeal cooling of the bloodstream and surface cooling of the body Extracorporeal cooling of the blood (Delorme 1953, Ross 1954) has the advantage that it can be initiated after surgery has begun and the exact nature of the lesion has been determined, but it has the disadvantage of complexity, of causing considerable biochemical disturbances (Brewin et al 1956), and of provoking cardiac irregularities more often (Graham 1955) Surface cooling has as its great merits simplicity and lack of gross physiological disturbance

I describe here the method of surface cooling used for open heart surgery at the Middlesex Hospital So far 32 patients have been subjected to open cardiac surgery 26 for the repair of atrial septal defects and 6 for the relief of pulmonary stenosis There have been no deaths and few complications

We have followed closely the method developed by Swan et al (1955) at the University of Colorado School of Medicine, and it is a pleasure to acknowledge their valuable help and guidance during a visit to Denver We have modified their technique as regards temperature level and rapid surface rewarming This rewarming, together with close surgical cooperation and effective "dovetailing" of the several stages of the procedure, has reduced to three hours the time from induction of anæsthesia to the return of the rewarmed patient to the ward The time factor is of some importance in view of the number of cases awaiting surgery and the need to avoid disruption of ward and operating-theatre routine

Ours has been a team project and I am indebted to my surgical, cardiological, and anæsthetist colleagues and to theatre, ward, and technical staff, who have all contributed to making the method practical The salient features of this method are

(1) Minimal anæsthesia using ether and muscle relaxants
(2) Surface cooling by blanket and cold bath
(3) A deep tissue temperature of 30°C during circulatory arrest
(4) Immediate rapid surface rewarming by blanket during surgery and by warm bath subsequently

These features are well illustrated in the chart (fig 1) of the operation *for an atrial* septal defect in a child of 6 years

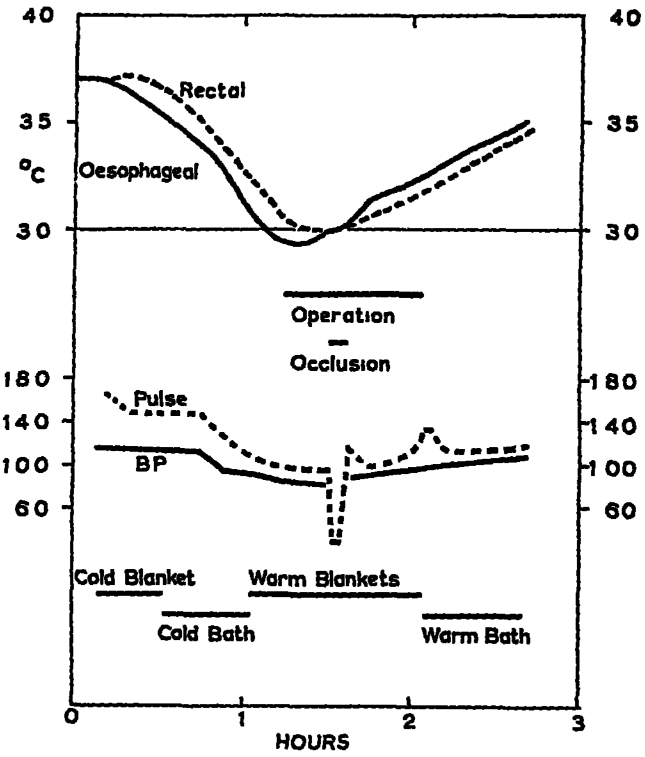

Fig 1—Repair of atrial septum under hypothermia in a child aged 6 years and weighing 40 lb

The Method

Anæsthesia

An hour after premedication with promethazine, pethidine, and scopolamine, anæsthesia is induced with thiopentone This is immediately followed by administration of succinylcholine and by oral intubation Anæsthesia is continued with nitrous oxide, oxygen, and ether Tubocurarine (' Tubarine ') is given to secure complete relaxation, and respiration is controlled throughout the entire procedure

Ether is used because it is less irritant to the cooling myocardium than are many other anæsthetic agents It causes vasodilatation and thus assists heat exchange When the patient has been cooled to the required temperature, ether is discontinued and most of what remains in the body is removed by vigorous ventilation This ensures that during the period of circulatory arrest the tissues—particularly the brain—are as free as possible from drugs During the operation anæsthesia is maintained by a sum of the depressant effects of hypothermia and its potentiation of the residue of the drugs not yet eliminated—the so-called " hypothermic anæsthesia " (Virtue 1955)

Cooling

As soon as induction of anæsthesia is completed, the patient is placed between plastic blankets through which water at 15°C is circulated Electric thermometers are placed in the œsophagus (to the level of the nipple line), *in the nasopharynx,* and in the rectum Intravenous drips are set up, and electrocardiographic leads and a blood pressure cuff are attached to the patient During this time some superficial cooling takes place, which helps to shorten the procedure

When these preliminaries are completed, the patient is immersed in a bath of water at 15–17°C, and shortly afterwards ice is added to keep the temperature of the water between 8°C and 10°C throughout the rest of the cooling

The gradual introduction to the cold environment is deliberate, so that the temperature of the venous blood returning to the heart shall not drop suddenly Immersion of a patient with dilated vessels in freezing water may well precipitate ventricular fibrillation It was the ease with which this catastrophe could occur in venous cooling in dogs that caused us to abandon this method in the experimental stages, when it was found that the temperature of the myocardium could rapidly become 6 or even 10°C cooler than the other tissues of the body

In the bath the patient's head and hands are supported above water After twenty minutes the toes are also lifted out to prevent undue chilling of the digits A towel soaked in cold water is placed over the patient so that the chest and knees, which tend to float above water, are effectively cooled and the maximum surface area is offered for heat exchange This towel also serves to satisfy those who criticise the method on æsthetic grounds The water is repeatedly stirred, and the superficial tissues of the patient are frequently massaged and kneaded to prevent stagnation of cold blood and to speed up heat exchange When the temperature of the bath water is maintained at about 10°C, there is no undue venospasm and circulation to the periphery remains reasonably good; thus heat exchange keeps pace with the superficial cooling and no large volume of cold superficial tissues is built up which might cause a profound drop in temperature after the patient has been removed from the bath

Temperatures are recorded every five minutes, and after a lag of from five to fifteen minutes they are found *to fall progressively, the rate of descent depending* on the relations of surface area to body weight Should the fall become retarded, or the patient shiver or develop excessive goose pimples, further ether and tubarine are given to overcome the body's attempts to increase heat production

As the body-temperature drops so does the heart rate, and by the time the operation is in progress it may be as low as 35–40 a minute The systolic blood pressure, which is low immediately after induction, rises on immersion in the bath, as a result of vasoconstriction, but it falls later to 80–90 mm Hg and remains at that level, except during circulatory arrest, until it rises again on completion of rewarming The radial pulse is palpable without difficulty during cooling Another sign of cooling is the gradual increase in the size of the pupils, which become widely dilated at temperatures below 30°C As cooling progresses, a distinctive pink coloration of the immersed skin is seen it is thought to be due to a combination of capillary stasis or paralysis and reduced metabolism in the skin The patient is removed from the bath when the œsophageal temperature reaches 31°C in children or 32°C in adults The time in the bath varies from about thirty minutes in a child weighing 40 lb to seventy minutes in a plump woman weighing 120 lb

Immediate Rewarming

The patient is removed from the bath, dried, and placed between plastic blankets through which water at a temperature of 40°C is now circulating The chest is exposed, and the arms are abducted to 90° and placed on arm rests angled upwards slightly to prevent damage to the brachial plexus

After drop

With hypothermia induced as thus described the after drop or drift in œsophageal temperature is about 2°C in adults and $1^1/_2$°C in children This drift takes place despite immediate rewarming with water blankets at 40°C The drift in nasopharyngeal temperature is usually 1°C more, but, as there is a lag of 1°C in the nasopharyngeal behind the œsophageal temperature, equilibrium is reached at or just below 30°C The after drift reaches its maximum in about twenty five minutes in children and forty minutes in adults

Operation

Ether is discontinued when the patient is removed from the bath Nitrous oxide is discontinued when the

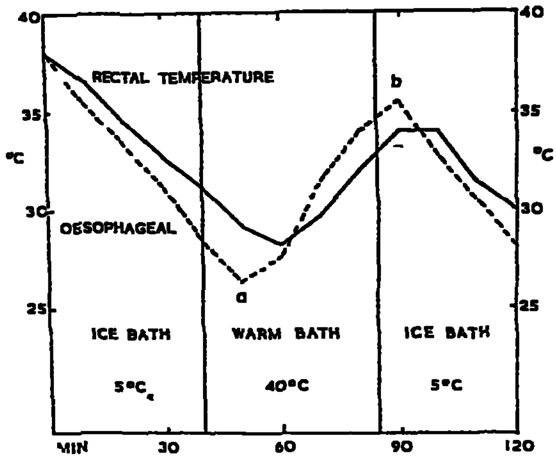

Fig 2—Experimental hypothermia in a dog weighing 34 lb

ncision is made, and vigorous controlled respiration is iaintained with pure oxygen until after the period of irculatory arrest This rapidly eliminates ether and llows diathermy to be used throughout the operation lood is given to replace that lost during exposure of the eart through the bilateral anterior incision, and an ttempt is made to reach optimum circulatory and espiratory conditions immediately before circulation is rrested Tourniquets are placed round the venæ cavæ, nd a clamp is placed through the transverse sinus ready o occlude the aorta and the pulmonary artery The ncision is made into the heart with a controlling clamp n place so that no unnecessary manœuvre should waste aluable seconds during the period of occlusion

After occlusion of the venæ cavæ, from ten to fifteen econds is allowed for the heart to empty, when neostigmine 0 03 mg per stone of body-weight is injected roximal to the aortic clamp (Prevedel et al 1954, Sellick 955) This reaches the coronary circulation and almost immediately slows the heart The controlling clamp is emoved, the heart is opened, residual blood is aspirated, nd the defect is repaired under direct vision During the eriod of circulatory arrest the lungs are kept gently nflated so that time is not lost in reinflating them when he circulation is restarted At the completion of closure f an atrial septal defect an increase in pressure on the bag nflating the lungs drives remaining blood from the lung nto the left atrium, excludes air, and demonstrates the atisfactory closure of the defect

The Time of Circulatory Arrest

The period of occlusion that can safely be tolerated by he brain and myocardium at 30°C is about ten minutes ew of our cases have taken longer than eight minutes he average has been five and a half minutes

In one case, in a man aged 26, after an occlusion of even and a half minutes, a tear was found in the inferior vena cava, and an immediate reocclusion of four minutes was needed to repair it Later in the operation a third occlusion, of two and a half minutes, was required to correct the venous return from the inferior vena cava into the right atrium This man showed no delay in recovering consciousness and no evidence of any cerebral damage and made an uneventful recovery

Subsequent Rewarming

After restoration of the circulation the blanket temperature is raised to 43°C, and, when a rising temperature shows that rewarming of the deep tissues has begun, 50% nitrous oxide is added to the oxygen When surgery is complete, a watertight dressing is applied to the wound, and the patient is returned to the bath and immersed at a temperature of 40°C By this time some rewarming has taken place from the water blankets In children the temperature may have reached 32°C and in adults 31°C by the completion of the surgery The warm bath is maintained at 40°C, and the same stirring and kneading technique is used as during the cooling The patient remains in the bath until an œsophageal temperature of 35°C is reached Spontaneous respiration is re-established, and residual curare is counteracted with atropine and neostigmine

After rise

A phenomenon similar to the after-drop occurs when the patient is removed from the warm bath and an after-rise in temperature is seen (fig 2, b) This after-rise is usually of the same order as the after-drop, and within an hour of return to the ward the patient is at normal temperature Consciousness is regained within an hour of removal from the bath As rewarming takes place, the size of the pupils returns to normal and is a good indication of the return of normothermic cerebral activity

Postoperative Care

The patient goes back to the ward with an oxygen mask and is then placed in an oxygen tent and nursed flat for eight hours Gentle suction is applied continuously to the thoracic drains to prevent pneumothorax After eight hours the patient is helped to sit up, by stages, and is taken out of the oxygen tent Methadone is used as an analgesic, and physiotherapy is begun as soon as possible

Results

In 32 cases open cardiotomy has been performed with circulatory arrest using this method of hypothermia 26 of the operations have been for the repair of an atrial septal defect (1 of these having an associated pulmonary valvular stenosis which was also corrected under direct vision at the same time, and 1 an associated mitral stenosis which was split digitally via the atrial defect), and 6 have been for the division of pulmonary stenosis (1 of these had a preoperative hæmoglobin of 188%)

Complications

There were no deaths During the operation auricular fibrillation and flutter often occurred when the body-temperature was at or below 30°C, but normal rhythm returned on rewarming Only 1 patient developed ventricular fibrillation, this happened at the onset of manipulation of the heart and coincided with a sudden change in pH due to replacement of a faulty soda lime canister in the anæsthetic circuit One shock from the electric defibrillator restored normal rhythm, and no further dangerous arrhythmia was observed There were no complications during cooling or during rewarming in the bath

After operation 2 patients developed pneumothorax despite intrathoracic drains One patient had a transient hemiplegia twelve hours after operation and a phlebothrombosis of the leg it was found later that his inferior vena cava drained partly into his left atrium, which probably explains his systemic embolism 2 patients sustained trivial superficial burns, both due to overheating in the rewarming blanket before a satisfactory thermostatic control was fitted

Discussion

Hypothermia is not a physiological condition, and our aim has been to keep its duration and depth to the minimum compatible with the proposed length of circulatory arrest Cooling in the bath is by far the most efficient means of heat exchange because the greatest possible surface area is exposed to the cooling medium On the other hand, excessively cold water, though possibly it cools the body more rapidly, produces vasospasm which delays transference of heat from the deep to the superficial tissues, with the result that a large volume of cold tissue is built up and the temperature may later fall unpredictably and often profoundly

Immediate surface rewarming made little difference to the degree of after drop in temperature after removal from the bath (fig 2, a), but it significantly shortened the hypothermia With skilled surgical coöperation it is possible to manipulate the heart during the period of maximum cooling of deep tissues—i e, at the lowest part of the curve (fig 1) The bilateral thoracotomy exposure of the front of the heart and the placing of tourniquets round the venæ cavæ are surprisingly speedy, and often the tourniquets have been in position before the lowest temperature was reached

Surface rewarming from deep hypothermia is said to be dangerous (Bigelow et al 1952), but our experience—after being disappointed with diathermy rewarming in the earlier cases—has been that rapid surface rewarming from 28°C does nothing but good, and we have seen no cardiovascular disturbances during it

Œsophageal temperatures have been taken as the criterion of the deep tissue temperatures The rectal temperatures were very unreliable and could indeed be dangerous if taken alone, for the lag that occurs if the rectal thermometer is insulated by fæces may well lead to excessive cooling In later cases nasopharyngeal temperatures were also recorded these followed more closely the œsophageal temperatures and can probably be taken as representing the temperature of the brain (Lucas 1956)

We think it unnecessary to lower the temperature below 30°C to provide a period of five to ten minutes' circulatory arrest At this temperature the risk of ventricular fibrillation is very slight, even in grossly enlarged hearts When hypothermia was first used, its dangers were undoubtedly magnified because temperatures as low as 26°C were considered necessary

Summary

A method of hypothermia for open heart surgery is described and discussed Its salient features are minimal anæsthesia using ether and relaxants, surface cooling by blanket and cold bath, deep-tissue temperature of 30°C during circulatory arrest, and immediate surface rewarming by blanket during operation and by warm bath subsequently

The results of 32 cases without mortality are reported

The integration of the effects of hypothermia and anæsthetic drugs make it convenient for the anæsthetist to be in over-all control of surface hypothermia and to report on the method used, but successful major cardiac surgery is the result of the work of a team which includes members from almost all departments of a large hospital

The method of hypothermic anæsthesia used at the Middlesex Hospital has been developed for open cardiac surgery in particular for the closure of atrial septal defects This project has involved close coöperation between cardiologists, surgeons, and anæsthetists

I am therefore particularly indebted to Dr D Evan Bedford and Mr T Holmes Sellors for their help and advice, and also to many other members of the team—surgical, medical, nursing, physiotherapy, and technical Facilities for experimental work on hypothermia were given me by the Institute of Clinical Research of the Middlesex Hospital

VACCINE LYMPH DEPARTMENT, LISTER INSTITUTE OF
PREVENTIVE MEDICINE, ELSTREE, HERTS

DURING recent years there has been increasing inter in the development of stable dried smallpox vacci in which the living virus could be preserved for lo periods at tropical temperatures Glycerinated vaccir lymph deteriorates rapidly at room temperature a thus has always been a major difficulty in the contr of smallpox in hot countries with poor transport facilit and inadequate refrigeration A stable dry vacc could, moreover, be stored with confidence as a reserve and thus ensure adequate supplies during an epidemi when immediate mass vaccination was essential Th ability to preserve virus preparations of known potenc in a dry state would also make it possible to mainta standards for international use and facilitate the com parison of strains of vaccinia virus from differe countries

This increasing interest is reflected in the extensive laboratory and field trials of dried smallpox vacci produced in several countries that have been carried out under the auspices of the World Health Organisation The results of these trials (1957) have shown that dried vaccines are available which are much more resistant to heat than any glycerinated vaccine lymph

The combined laboratory and field trials on the dried smallpox vaccine prepared at the Lister Institute have been continued over a longer period Since this advance in vaccine production is of great importance to tho responsible for vaccination campaigns in hot climate a summary of the results obtained in these trials i presented here

Materials and Methods

Preparation of Vaccine

This has been fully described by *Collier* (1955) Briefly, the vaccine consists of a suspension of vaccinia virus, partially purified by differential centrifugation and by exposure to phenol, in a solution of 5% peptone in distilled water The suspension is dried in a centrifugal freeze-drier and sealed under vacuum in phials of neutral glass These are dispensed together with the require amounts of reconstituting fluid in 25 dose and 100 do outfits Because of the small amounts of dried materi and the very small amounts of reconstituting fl required, it is not practicable to issue this vacc in single-dose tubes

The dried vaccine is of much greater purity than ordinary vaccine lymph, it is free from contaminating bacteria and tissue debris and in consequence produce less local secondary reaction Storage tests have shown that the virus is better preserved when sealed unde vacuum than in nitrogen, even when precautions are taken to remove traces of moisture and oxygen from the gas The reconstituting fluid is 40% glycerol in McIlvaine's buffer at pH 7 2 This is supplied in phials designed to obviate the need for sterilised syringes in transferrin the fluid to the dried vaccine The risk of contamination is thus reduced

Storage of Vaccine

Samples of the dried vaccine were stored at –10°C, 37°C, and 45°C. A batch of glycerinated vaccine lymph was also maintained at –10°C throughout the experiment to control the susceptibility to vaccination of the rabbits used in potency titrations and of the people on whom the vaccine samples were tested.

Samples of the vaccine stored at –10°C were tested at the beginning and end of the trial. Samples stored at 37°C and 45°C were removed at intervals from 4 weeks to 106 weeks (approximately 2 years) for titration in the laboratory and trials in primary vaccination in man. Samples are still being maintained at the higher temperatures to detect any future deterioration.

In addition, samples from some other batches of vaccine selected at random were stored at 37°C and 45°C for 8 weeks and then tested in the same way to ensure that the batch used in the trial was not exceptional in its resistance to heat.

Titration of Stored Samples

All potency titrations were duplicated in the department of bacteriology of the University of Liverpool and in the Lister Institute, Elstree. At the start of the trial, titrations were done on the dried vaccine and the glycerinated lymph held at –10°C and subsequently on the dried vaccine stored at 37°C and 45°C. Thus each sample was titrated in the laboratory at the time of issue for clinical trial. Finally, at the end of the trial, samples of the dried vaccine and the control lymph held at –10°C were again titrated to ensure that there had been no deterioration at that temperature.

Titrations by scarification in rabbit skin.—These were duplicated on the clipped backs of two rabbits in each laboratory. Dilutions of vaccines were made in McIlvaine buffer, 0.01 M phosphate at pH 7.4. Volumes of 0.1 ml. of the appropriate dilution were spread over areas of about 5 sq. cm., and the skin was lightly scarified through the fluid. Threefold dilutions from 1:1000 to 1:27,000 were tested, and the glycerinated lymph was titrated on each rabbit to control its susceptibility to vaccinia virus. The lesions were recorded on the 5th and, if necessary, 6th days.

Titrations on chick chorio-allantoic membrane.—The technique of this test has been described in detail in the report on the W.H.O. trials in the *Bulletin of the World Health Organisation* (1957). Here it is only necessary to state that 0.1 ml. amounts of the appropriate dilutions of vaccine were inoculated on the dropped chorio-allantoic membranes of groups of five or six 12-day chick embryos for every dilution tested. After 48 hours' incubation at 35°C the dropped areas of the membranes were removed and washed, and the lesions were counted. Titres were expressed as infectious units per ml. of undiluted vaccine (i.u. per ml.) and were computed from the mean pock count at the lowest dilution giving discrete countable pocks.

Vaccinations

Thanks to the cooperation of the directorate of hygiene and research of the Royal Air Force and of the Headquarters Technical Training Command, in particular of the Principal Medical Officer there, Air Commodore J. Hill, sufficient volunteers were available for vaccination.

Young men with no history of previous vaccination and without scars on their arms were selected for vaccination with the samples under test. In the first instance groups of men were vaccinated with the dried vaccine and with the glycerinated lymph held at –10°C to ensure that both vaccines produced 100% of successes. Thereafter the dried vaccines stored at 37°C and 45°C were each tested in groups of about a hundred men up to 78 weeks' storage. The size of the control group vaccinated with lymph was reduced to about fifty after the earlier tests and, in view of the successful results already obtained, the size of the groups tested with dried vaccines at 106 weeks was also reduced to about eighty.

All the vaccinations were made by one of us (R. M. C.) by a uniform technique—a single linear scratch $^1/_4$ inch long. Arms were inspected on the 7th day and the results recorded as "vesiculation" or "no vesiculation". No other distinction was made.

Results

Resistance at 37°C and 45°C

The results of the laboratory titrations and of the vaccinations after storage for 32, 64, and 106 weeks are shown in the accompanying table. Samples were in fact withdrawn for test after storage for 4, 8, 16, 32, and 78 weeks, but, in view of the uniformly satisfactory results obtained at the later tests, it is unnecessary to include all the earlier ones in the table.

It will be seen that there was no detectable deterioration either by pock counting or scarification tests after 32 weeks' storage at 37°C and 45°C. Vaccination with these samples also produced 100% of successes. After 64 weeks' storage there was no detectable deterioration by pock counting in the sample stored at 37°C, though there might have been a slight decrease in the potency measured on the rabbit. The sample stored at 45°C showed a slight but possibly significant decrease in potency by both pock counting and rabbit titration. Both samples still produced 100% of successful vaccinations.

After 2 years (106 weeks) there was still no detectable decrease in the pock count of the sample stored at 37°C, though there was some apparent decrease in the potency measured in rabbits. The sample stored at 45°C showed a slight further decrease in pock count measured in one laboratory but not in the other. The samples stored at both temperatures still produced 100% of successful

Survival of dried smallpox vaccine in water at 100°C

vaccinations, there was no evidence of any modification of the vesicular lesions obtained and no difference between the reactions produced by the samples stored at the higher temperatures and by those kept at –10°C

Resistance at 100°C

Phials of dried vaccine from two different batches were immersed in boiling water Two phials were removed at each sampling-time after exposure to this temperature for periods of from 30 up to 120 minutes and titrated separately by pock counting The results are shown in the accompanying figure Each point on the graph is the arithmetic mean of the titres of surviving virus in the pair of phials

The initial titre of the virus was 6 0 × 10^8 p u per ml After 30 minutes the titre had fallen to 3 0 × 10^8 p u per ml and after 60 minutes to 6 0 × 10^7 p u per ml Thereafter there was no further detectable fall in titre up to 120 minutes Thus the vaccine from these two batches after 2 hours' exposure to 100°C contains sufficient living virus for 100% of successful vaccinations Since the dried material was in direct contact with the glass of the phial, it can be assumed that during the heating its temperature was not far short of the surrounding boiling water

Heat Resistance of Other Batches

Samples from seven other batches of dried vaccine selected at random were stored at 37°C and 45°C for 8 weeks After this period the samples stored at 45°C were each tested on groups of at least twenty five men and produced 100% of successful vaccinations Although when titrated by pock counting some of these batches showed slight deterioration at this temperature, the result of this test shows that the batch of vaccine used in the main storage test was not exceptionally heat-resistant

Comment

Public health authorities responsible for vaccination programmes involving the transport and storage of smallpox vaccine in hot climates with inadequate refrigeration will be relieved to know that a stable vaccine is available which will resist tropical temperatures for many months They will also be able to maintain reserves available for immediate distribution in epidemics, if these reserves are held in refrigerators they should have a very long life indeed So far we have not been able to detect any deterioration in refrigerated dried vaccine during periods of up to 2 years

Summary

The results of tests on a dried smallpox vaccine stored at 37°C and 45°C for up to 2 years are recorded

At the end of this period the vaccine stored at the higher temperature still produced 100% of successful vaccinations in man and showed only a slight decrease in potency by laboratory titration

A dried smallpox vaccine with such resistance to heat should solve the major difficulty in carrying out vaccination programmes in hot countries with poor transport and inadequate refrigerating facilities It would also enable adequate reserves to be held in these countries against epidemics.

The coöperation of Prof A W Downie, F R S, and Dr K R Dumbell, of the department of bacteriology, University of Liverpool, in the laboratory titrations of the vaccine is gratefully acknowledged

PARTIAL MEGALOBLASTIC ERYTHROPOIESIS

IN ELDERLY ACHLORHYDRIC PATIENTS WITH MILD ANÆMIA

DURING 1955 we tried to estimate the incidence of vitamin B_{12} deficiency in mainly elderly patients with histamine refractory achlorhydria This group was selected as being likely to contain cases with vitamin B_{12} deficiency because pernicious anæmia is associated with histamine refractory achlorhydria and is most common in the elderly

The primary diagnostic criteria of vitamin B_{12} deficiency were typical (Ehrlich) megaloblasts in the sternal bone-marrow and a typical response to treatment with vitamin B_{12} Supplementary investigations, including estimation of the level of vitamin B_{12} in the blood plasma, were also made

In this way we discovered quite a high frequency of patients with incipient or partial megaloblastic erythropoiesis and mild anæmia This group was compared with a group of achlorhydric patients with complete megaloblastic erythropoiesis (typical pernicious anæmia) Deficiency of iron and of vitamin C was common in both groups, especially the women—a finding which is of particular interest, because it makes the diagnosis of vitamin B_{12} deficiency more difficult

Material

The "*incidence material*" came from Medical Department E of the Frederiksberg Hospital, Copenhagen, and comprised all the cases diagnosed in 1955 as histamine refractory achlorhydria and subjected to a study of the bone marrow (which was done in as many of the patients as was practicable) These cases were compared with achlorhydric patients seen in 1954 (table I)

The "*compared material*" consisted of 13 achlorhydric patients with megaloblastic erythropoiesis observed in 1954 and 1955, supplemented by similar cases seen in 1956 to get two equally large groups of consecutively studied patients, one including 10 patients with total megaloblastic and the other 10 patients with partial, megaloblastic erythropoiesis

TABLE I—FREQUENCY OF STERNAL MARROW STUDIES AND INCIDENCE OF MEGALOBLASTIC ERYTHROPOIESIS IN PATIENTS WITH HISTAMINE-REFRACTORY ACHLORHYDRIA

Year	No. of patients admitted			No. examined for histamine refractory achlorhydria	No. with histamine refractory achlorhydria	No. submitted to sternal puncture	No. with megaloblastic erythropoiesis
	M	F	Total				
1954	907	1147	2054	384 (*18·5%*)	72 (*18·7%*)	30 (*41·7%*)	6 (*20·0%*)
1955	940	1228	2168	389 (*17·8%*)	93 (*23·9%*)	63 (*67·7%*)	13 (*20·6%*)

In addition, there were the patients with achlorhydria, ormoblastic erythropoiesis, and mild anæmia whose itamin-B$_{12}$ level in the plasma had been determined nd two control series of "healthy" elderly persons in one f which serum-vitamin-B$_{12}$ levels and in the other serum-ron levels had been determined.

Diagnosis and Treatment

Methods

The indications for examining a patient for achlorhydria were those ordinarily used in the department, especially astro intestinal complaints and anæmia. When histamine-efractory achlorhydria (fractional withdrawal of gastric uice for 60 minutes after subcutaneous injection of histamine ydrochloride 0·5 mg.) was found, we did a sternal puncture nd examined the blood in the ordinary way—hæmoglobin evel (100% = 14·8 g. of Hb per 100 ml.), red cell count, olour index $\frac{\text{Hb}\%}{(\text{erythrocytes (mill.)} \times 21)}$ total and differential hite cell counts, reticulocyte counts, and determination of he serum iron level by the method of Hoyer (1950) and of he ascorbic acid level (dichlorphenolindophenol method). If egaloblastic erythropoiesis was found, the level of vitamin B$_{12}$ in the plasma was determined by one of us (H. P. O. K.) using the *Lactobacillus leichmannii* 313 (Kristensen 1956).

The sternal marrow was examined (by A. S. O.) partly in sections after coagulation and mounting and partly in smears stained by the method of May Grünwald-Giemsa. Megaloblasts and promegaloblasts were counted and recorded per 400 white cells. Total megaloblastic erythropoiesis is taken to mean that the only red cells were promegaloblasts and megaloblasts, whereas in partial megaloblastic erythropoiesis there were both normoblasts and megaloblasts. Megaloblastic erythropoiesis was diagnosed only when megaloblasts and promegaloblasts of the classical Ehrlich type were found. The discovery of maturation disturbances of the granulocytes with pernicious anæmia neutrophils" without typical changes in the erythroblasts—interpreted during recent years as a mild deficiency of antimegaloblastic substances (Jones 1943, Fox et al. 1950, Bastrup Madsen 1954, Jewesbury 1954)—indicated the need for repeated examination, often after energetic treatment with iron. The same applies to the discovery of megaloblast like cells" "intermediary megaloblasts" and macronormoblasts."

Other tests included examination of the fæces for blood, kidney function tests, radiography of the stomach and intestines to detect cancer, sprue, strictures, &c., determination of the excretion of fat in the stools, and (in most cases) Coombs's test.

Many patients were treated first with iron and ascorbic acid, partly because of low serum iron levels and partly to accelerate, if possible, a megaloblastic alteration of the bone-marrow, which did not initially satisfy our criteria of megaloblastic erythropoiesis. When the diagnosis of megaloblastic erythropoiesis had been established, we administered vitamin B$_{12}$ parenterally (cyanocobalamin 30–60 µg. daily for ten days). Treatment was continued with liver preparations ('Hepsol Fortior') or an oral combined preparation ('Cycoplex' capsules, each containing dried pyloric mucosa 50 mg. and vitamin B$_{12}$ 5 µg.), as well as iron and ascorbic acid. The patients were kept in hospital as long as necessary and were followed up after discharge. Their blood and bone marrow were repeatedly examined to ascertain whether the erythropoiesis had returned to normal, the hæmoglobin level and erythrocyte count had satisfactorily increased, and the levels of iron, ascorbic acid, and vitamin B$_{12}$ had become normal.

Criteria

The diagnosis of *iron deficiency* was established by an increase in the reticulocytes and the colour index during iron medication (either oral or parenteral) before antimegaloblastic treatment. Since the effect of iron was not specially investigated in all the cases, other criteria were also used (see below).

The diagnosis of *vitamin-C deficiency* was established by a serum ascorbic acid level of 180 µg. or less per 100 ml., followed by an increase to normal after treatment with ascorbic acid.

The diagnosis of *vitamin-B$_{12}$ deficiency* was established by a decrease in the megaloblastic erythropoiesis in direct time relation to treatment with pure cyanocobalamin accompanied by a typical fall of the serum iron level and an increase in the reticulocytes followed by an increase in the red cells to 4,500,000 per c.mm. in uncomplicated cases.

The diagnosis of *nephrogenous hæmolytic anæmia* was established by a spontaneous reticulocytosis of at least 4% after an abrupt decrease in the hæmoglobin and the red cells or persistent spontaneous reticulocytosis of at least 2% in patients with impaired renal function.

Results and Comments

"INCIDENCE MATERIAL"

In table I the material of 1955 is compared with that of 1954. Twice as many achlorhydric patients had their bone-marrow examined in 1955, and twice as many cases of megaloblastic erythropoiesis were found, as in 1954. The frequency with which the erythropoiesis of the cases submitted to bone marrow study was interpreted as megaloblastic (20%) was unchanged from 1954 to 1955. Moreover the frequency with which the patients were examined for achlorhydria was the same (18%). Since, furthermore, achlorhydria was found only slightly more often in 1955, the findings indicate that technique, indications, and interpretation had not changed in 1955 except for the more frequent examination of the bone-marrow.

The frequent bone-marrow studies in achlorhydric patients in 1955 seem to be the main reason why the number of patients with newly diagnosed megaloblastic erythropoiesis was doubled.

Of the 93 patients (30 men and 63 women) in 1955 with histamine refractory achlorhydria 7 had incipient or partial megaloblastic erythropoiesis. These patients belonged to the group of 51 who satisfied the criteria of mild anæmia (Hb 51–84%), age over 50, and no definite signs of pernicious anæmia. Of these 51 patients 5 did not have their bone-marrow studied, but, since they did not differ in other respects from the remaining 46

TABLE II—AVERAGE FINDINGS IN 51 ACHLORHYDRIC PATIENTS SEEN IN 1955, AGED 50 OR MORE, WITH MILD ANÆMIA BUT WITHOUT MANIFEST PERNICIOUS ANÆMIA (TOTAL MEGALOBLASTIC ERYTHROPOIESIS)

—	Erythropoiesis (sternal marrow)			
	Normoblastic	Partially megaloblastic	Total	Not examined

Colour index	0·95	1·05	0·96	0·98
Serum iron level (µg. per 100 ml.)	54	56	51	43

TABLE III—FINDINGS IN 10 PATIENTS (7 FEMALES AND 3 MALES) WITH TOTAL AND 10 (8 FEMALES AND 2 MALES) WITH PARTIAL MEGALOBLASTIC ERYTHROPOIESIS BEFORE AND AFTER TREATMENT

Finding	Megaloblastic erythropoiesis			
	Before treatment		After treatment	
	Total	Partial	Total	Partial
Age (yr.)	41–81 (av. 66)	53–87 (av. 69)		
Promegaloblasts and megaloblasts in bone marrow				
Per 100 "white" cells	678–177 (av. 310)	101–11 (av. 55)		
Per 100 "red" cells	100 (av. 100)	91–11 (av. 43)		
Hæmoglobin (%)	33–63 (av. 45)	51–83 (av. 71)	88–111 (av. 100)	85–100 (av. 9
Red cells (millions per c.mm.)	1·13–2·21 (av. 1·65)	2·15–4·62 (av. 3·11)	1·62–5·17 (av. 4·98)	4·02–4·56 (av. 4·
Colour index	1·16–1·56 (av. 1·30)	0·96–1·11 (av. 1·09)	0·85–1·07 (av. 0·96)	0·91–1·07 (av. 1·
Serum iron (µg. per 100 ml.)	15–200 (av. 120)	7–109 (av. 76)		
Plasma level of vitamin B_{12} (µµg. per ml.)	10–85 (av. 52)	55–205 (av. 127)		
Serum ascorbic acid (µg. per 100 ml.)	90–180 (av. 143)	20–160 (av. 144)		
Highest reticulocyte count after vitamin B_{12} therapy (per 1000 red cells)			62–276 (av. 115)	20–200 (av.

(table II), the incidence of partial megaloblastic erythropoiesis was very probably the same, therefore we can disregard these 5 in computing the incidence. The 46 patients thus make up a series in which the incidence of partial megaloblastic erythropoiesis can be computed. The result is as follows: in 46 consecutive patients, aged more than 50, with histamine-refractory achlorhydria and mild anæmia but no definite signs of pernicious anæmia, the bone marrow showed that 7 had incipient or partial megaloblastic erythropoiesis.

Table II shows that the sex-distribution in the series is so unequal that the incidence of partial megaloblastic erythropoiesis seems to be about 20% for women (7/38) and is unknown for men (0/8). The same table shows that the difference between the 7 patients with partial megaloblastic erythropoiesis and the others as regards age, hæmoglobin level, red-cell count, colour index, and serum iron level is so slight that the true nature of the erythropoiesis will very easily escape detection if the bone marrow is not examined (see also discussion below).

"COMPARED MATERIAL"

Table III gives average data for 10 cases of total and 10 cases of partial megaloblastic erythropoiesis. The data for the 10 patients with partial megaloblastic erythropoiesis have already been reported by Pedersen et al. (1957b).

Sex and Age

The distribution is the same in both groups.

Bone marrow

As might be expected, the greatest changes were found in patients with total megaloblastic erythropoiesis. In partial megaloblastic erythropoiesis about 10–90% (average 43%) of the erythroblasts were megaloblastic. In 3 cases definite Ehrlich megaloblasts did not develop until intensive treatment with iron had been given, and in 2 cases macroforms in the granulocytes (e.g., giant metamyelocytes) were seen when typical megaloblasts were not yet present.

Hæmoglobin, Erythrocyte count, and Colour index

In the 10 patients with total megaloblastic erythropoiesis these factors were typical of pernicious anæmia. All the patients with partial megaloblastic erythropoiesis had mild anæmia, but a few were at the limit of normal. Later we had occasion to diagnose partial megaloblastic erythropoiesis in non-anæmic patients, as might be expected. The colour index was surprisingly low in this group (average 1·09). Only 3 of the 10 had a colour index above normal (≧1·15), and in 2 cases the colour index was <1·00. In the patients with partial megaloblastic erythropoiesis the blood smears showed some macrocytosis of the red cells, but the variations in their size were not thoroughly examined. Like the erythrocyte counts, the average leucocyte and thrombocyte counts were decreased, mostly in patients with total megaloblastic erythropoiesis. Lymphocytosis too was more pronounced and macropolycytes were more commonly seen in total megaloblastic erythropoiesis.

Serum iron Level

On the average, the levels were only 120 and 76 µg. per 100 ml. in total and in partial megaloblastic erythropoiesis respectively. In the 5 men it was 150 µg. per 100 ml. and in the 15 women 81 µg. per 100 ml. In comparison, in 9 men and 9 women aged more than 50 (average 65) without anæmia and with normal gastric secretion the serum iron levels were 107 and 103 µg. per 100 ml. respectively (Pedersen et al. 1957a). Thus, whereas the men had a raised serum iron level, as might be expected in pernicious anæmia, the women, both those with total and those with partial megaloblastic erythropoiesis, had a lower serum iron level than normal. Without doubt the main cause of this low initial serum iron level was iron deficiency (Pedersen et al. 1957a). In 5 patients with an initial serum-iron level of 100 µg. per 100 ml. at the most we observed a reticulocytosis, and an increase in the colour index and sometimes in the hæmoglobin during intensive treatment with iron before antimegaloblastic treatment was instituted. Afterwards, the latter caused a second typical reticulocytosis and a fall in the serum-iron level.

In addition, the following facts gave indirect proof of iron deficiency:

(1) Some initial serum iron levels were so low (≦8 µg. per 100 ml.) that they were only explicable by iron deficiency.

(2) When the initial serum iron levels were somewhat higher (up to 100 µg. per 100 ml.) we found such low values (≦30 µg. per 100 ml.) immediately after the institution of antimegaloblastic therapy that iron deficiency must be considered proved.

(3) As mentioned above, iron and ascorbic acid were often administered before antimegaloblastic therapy was started. Lately we routinely continued or instituted this treatment with iron and ascorbic acid at the same time as specific therapy. Despite this iron medication we found serum iron levels of ≦10 µg. per 100 ml. in several patients after having administered specific therapy for some time. In some of the

cases it was necessary to give an intravenous injection of about 2–3 g of iron before the iron deficiency was overcome

In the present series 16 of the 20 patients appear to have had iron deficiency which was demonstrable, in most of the cases, at the time when megaloblastic erythropoiesis was diagnosed Both groups of patients with megaloblastic erythropoiesis, particularly the women, characteristically had vitamin-B_{12} deficiency and iron-deficiency anæmia It seems characteristic also that the iron deficiency was traced back to hæmorrhage in only 2 cases

Plasma-vitamin-B_{12} Level

In 19 cases the vitamin-B_{12} level in the blood-plasma was determined on one to three occasions before anti-megaloblastic therapy was instituted In the patients with total megaloblastic erythropoiesis the vitamin-B_{12} level was, as expected, very low (average 52 μμg per ml) In the patients with partial megaloblastic erythropoiesis the corresponding value was 127 μμg per ml (in 4 cases <100, in 3 cases 100–150, and in another 3 >150 μμg per ml) Table IV, which also gives the intra-individual variation, compares these two groups with a group of patients with achlorhydria but without megaloblastic changes in the bone marrow (from the "incidence material") and with a group of "healthy" persons in whom the gastric secretion and sternal bone marrow were not examined In the last two groups the average values were 275 and 395 μμg per ml respectively The average values conform to the degree of megaloblastic alteration in the bone marrow in the three achlorhydric groups In addition, the table makes clear the far from surprising fact that pernicious anæmia does not comply with an all or nothing law Although the four groups overlap, the agreement between the bone marrow findings and the vitamin B_{12} levels in the plasma is so good that determination of the latter can apparently restrict the number of patients who need a bone marrow examination or other tests, when a deficiency of vitamin B_{12} is suspected

TABLE IV—PLASMA LEVEL OF VITAMIN B_{12} IN ANÆMIC PATIENTS WITH HISTAMINE REFRACTORY ACHLORHYDRIA AND IN HEALTHY NON ANÆMIC PEOPLE

Group	Age (yr)	No of persons	Histamine refractory achlorhydria	Megaloblastic erythropoiesis	Plasma level of vitamin B_{12} (μμg per ml)
Severe anæmia (Hb 45 %)	44–84	10	+	Total	10–100 (av 52)
Mild anæmia (Hb 71 %)	53–87	10	+	Partial	(40) 70–220 (av 127)
Mild anæmia (Hb 70 %)	50–86	26	+	None	88–725 (av 275)
Healthy people* (Hb ≧ 85 %)	67–88	29	Not examined	Not examined	190–770 (av 395)

* Kristensen's (1956) series

Serum ascorbic acid Level

The initial serum ascorbic acid level was estimated in 15 of 20 patients and found to be low in 12 (extremely low in some of them) There was no difference between the two groups, hence the vitamin-C deficiency may be added to the iron deficiency and the vitamin-B_{12} deficiency as a characteristic of both groups

Tongue Signs and Neurological Signs

Of the patients with total megaloblastic erythropoiesis 7 presented objective tongue signs and 3 loss of reflexes, whereas of those with partial megaloblastic erythropoiesis 5 had objective tongue signs and 3 paresis or loss of reflexes

Clinical Types with Partial Megaloblastic Erythropoiesis

The patients in this group appear to fall into two clinical types

(1) An ordinary pernicious anæmia type (in our series 4 elderly grey haired blue eyed women in a good nutritional state—e g , case 1)

(2) The other type—represented by 4 or 5 cases—was characterised by its complications and by the multiple origin of the anæmia Patients in the second category might present—in addition to anæmia with deficiencies of iron, vitamin C, and vitamin B_{12}—nephrogenic, more or less hæmolytic, anæmia as well as infectious and/or toxic anæmia—e g , case 3

Case 2 represents a transition between these two types

Illustrative Case reports

Case 1 *sideropenic anæmia + megaloblastic anæmia* —A woman, aged 74, somewhat arteriosclerotic but otherwise well preserved, was admitted in 1953 with degenerative osteo arthritis of the knees and Hb 91%, and readmitted in 1954 with the same condition and Hb 85%, red cells 4,040,000 per c mm , and colour-index 1 00 In 1955 she was admitted complaining of intermittent diarrhœa She had Hb 72%, red cells 3,520,000 per c mm , colour index 0 90, serum iron level 37 μg per 100 ml , and serum ascorbic acid level 122 μg per 100 ml Histamine test showed achlorhydria, and plasma vitamin-B_{12} level was 120 μμg per ml Sternal puncture revealed normoblastic erythropoiesis, but the granulocytes showed large neutrophil forms with hypersegmented nuclei After intensive iron medication the Hb increased to 85% and the colour index to 1 10, and there was a simultaneous increase in the reticulocytes A month later there was unequivocal partial megaloblastic erythropoiesis, and the plasma-vitamin B_{12} level was 135 μμg per ml Administration of vitamin B_{12} produced a renewed increase and decrease in the reticulocytes and a return of the bone marrow to normal The other usual hæmatological data did not become normal, however, until intensive treatment with iron, vitamin C, and hepsol had been continued for ten months The only reasons that could be suggested were arteriosclerosis and old age , there were no radiological changes in the stomach and intestines and no increased excretion of fat in the fæces

Case 2 *sideropenic anæmia + megaloblastic anæmia + mild nephrogenic anæmia* —A woman, aged 53 who for the past twenty-three years had noticed burning of the tongue and had been receiving "acid tablets" for many years, had been admitted many times to other hospitals with migraine, muscle pain, and nervousness During the past six months she had been getting ever more tired and nervous A month before admission she entered the psychiatric department of our hospital with the diagnosis of mental depression and hysteria During her stay there her Hb decreased from 89 to 74%, red cells from 3,950,000 per c mm to 3,500,000 per c mm , and colour-index from 1 08 to 1 00 Sternal marrow showed incipient megaloblastic erythropoiesis The serum iron level was 68 μg per 100 ml , the ascorbic acid level 120 μg per 100 ml , and the plasma vitamin B_{12} level 85 μμg per ml Treatment, first with iron and vitamin C and later with vitamin B_{12} produced an increase and decrease of the reticulocytes on both occasions and a return of the sternal bone marrow to normal after vitamin B_{12} therapy It was not until the treatment had been given for six months however, that the blood values became satisfactory In addition to iron deficiency and vitamin B_{12} deficiency the patient had chronic pyelonephritis with occasional albuminuria and colipyuria (treated with various antibiotics) and slightly impaired renal function After treatment she felt "completely transformed", her tongue signs and fatigue had disappeared

Case 3 *sideropenic anæmia + megaloblastic anæmia + nephrogenic anæmia with hæmolytic component + toxic infectious anæmia* —A woman, aged 55, had been admitted several times during the past ten years with various muscle pains, colitis, pyelitis (*Esch coli*) and poisoning with phenacetin A month before admission to our department her Hb was 80%, red cell count 3,340,000 per c mm , and colour index 0 94 She had previously been energetic and efficient but during the past few years things had gone wrong She had not been out of doors for the past eighteen months and had been confined to bed for the past nine months (partly because of a fracture of the spine). She was known as a phenacetin addict and often had to be given injections of morphine by the night doctor. She was transferred from the psychiatric department because of pain in her abdomen and loin, malaise, nausea, and vomiting. She had flaccid muscles and was anæmic, yawning, sleepy, grey cyanosed like "tablet eaters," and looking more debilitated at first glance than later. Her Hb was 67%, colour index 1.20, serum iron level 52 µg per 100 ml., ascorbic acid level 130 µg per 100 ml., and plasma vitamin B_{12} 203 µµg per ml. Sternal marrow showed partial but severe megaloblastic erythropoiesis. During the first few days her temperature rose, and on the sixth day colibacillæmia was found. Blood-transfusion, iron, ascorbic acid, and vitamin B_{12} produced a striking increase in reticulocytes (20%) on the seventh day after the start of vitamin-B_{12} therapy, but at the same time the Hb decreased to 43% and the colour index to 1.07. This was no doubt because of a hæmolytic crisis due to the colisepsis in connection with kidney disease (albuminuria 0.8 g. per 100 ml., impaired power of concentration), and methæmoglobinæmia (0.8 per 100 ml.). However, on the fourteenth day of vitamin B_{12} therapy the erythropoiesis was normoblastic. The infection was treated with penicillin, streptomycin, and erythromycin and eventually responded after four weeks' treatment. Thereupon the blood values rapidly increased. Provocative doses of phenacetin and sulphathiazole did not produce any reticulocytosis or decrease in Hb. By energetic training and continued treatment of the anæmia we got the patient out of bed. She put on 7 kg in weight, her erythrocyte sedimentation rate fell, and she was "feeling better than in the past fifteen years." After her discharge the blood values tended to fall slightly when she began "tablet eating" again (methæmoglobinæmia 0.5 per 100 ml.).

Response to Treatment

In the patients with total megaloblastic erythropoiesis the reticulocytes and other blood values increased appropriately in a reasonable time (table III). On the treatment used, the levels of vitamin B_{12}, iron, and ascorbic acid in the serum were fairly easy to keep normal.

In the patients with partial megaloblastic erythropoiesis the increase in reticulocytes after treatment with iron + ascorbic acid and with vitamin B_{12} was also appropriate in view of the high initial values of Hb and red cells (table III). The bone-marrow was immediately rendered normoblastic by vitamin B_{12} therapy, and the ascorbic acid and vitamin-B_{12} levels in the serum rapidly returned to normal. On the other hand, it was difficult to keep the serum iron levels normal in some patients, who required 2–3 g. intravenously for a few months before this was accomplished. It was also difficult to obtain a sufficient increase in the Hb and red cells in these patients. This was explained partly by the presence of anæmia of multiple origin, but often six months' intensive treatment with iron, ascorbic acid, and vitamin B_{12} was necessary, also in the ordinary pernicious anæmia type. In 3 patients no explanation other than arteriosclerosis was found. The most intensive therapy was necessary in the patients with partial megaloblastic erythropoiesis, but it was extremely successful when the complications were not too disabling.

Discussion

Incidence of Partial Megaloblastic Erythropoiesis

So far as we know, no other study on partial megaloblastic erythropoiesis, confirmed by sternal puncture, in achlorhydric people has been published; but its incidence, as found by us, fits in with recent studies on the incidence of gastric atrophy and reduced absorption of radioactive vitamin B_{12} in achlorhydric people.

From biopsies of gastric mucosa in 42 cases of hypochromic anæmia Davidson and Markson (1955) concluded that anæmia might coexist with a normal stomach, with atrophic gastritis, and with gastric atrophy. There were no specific changes of the gastric mucosa in hypochromic anæmia, although abnormalities were more common than in a control series of 31 non-anæmic patients. Gastric atrophy was equally common in both groups—10% and 13% respectively. From their data it can be calculated that 24 patients (20 with secondary anæmia and 4 without anæmia) had histamine-refractory achlorhydria, and that 7 of them had gastric atrophy either equal to or approaching that which is typical of pernicious anæmia.

Badenoch (1954), examining biopsy specimens from 24 patients with hypochromic anæmia and achlorhydria, found severe gastric atrophy in 7. In 1 of them the changes were indistinguishable from the atrophy of pernicious anæmia, and in 6 the changes approached this form of atrophy. In 4 of the patients the absorption of radioactive vitamin B_{12} was decreased.

Finally, Schilling et al. (1955), studying 31 patients with various diseases but all with histamine-refractory achlorhydria without "laboratory evidence of pernicious anæmia," found decreased absorption of vitamin B_{12} in 8.

We have added figures from the above studies to those derived from the present study. The results are as follows: of 48 patients with histamine-refractory achlorhydria with or without anæmia 14 had gastric atrophy (in other words, they ran a great risk of developing pernicious anæmia); in 12 of 55 such patients the quantity of intrinsic factor was reduced (i.e., they were already developing pernicious anæmia); and 7 of 46 such patients had unequivocal megaloblastic erythropoiesis, probably due to incipient pernicious anæmia in most cases.

If we disregard the number of patients, their age distribution, diseases, &c., the trend of these figures suggests that the incidence of partial megaloblastic erythropoiesis found by us is probably not too high. Moreover Davies (1931), in a careful study of the peripheral blood of 15 patients with histamine-refractory achlorhydria and secondary anæmia, found indubitable "dimorphous anæmia" in 2.

Iron Deficiency Combined with Vitamin B_{12} Deficiency

Most of the patients in the "compared material" had anæmia due to iron deficiency and vitamin B_{12} deficiency. The frequent coexistence of these two deficiencies, especially in women, has been emphasised by Whitby and Britton (1953), and Trowell (1943, 1944) used the designation dimorphous anæmia for this combination in African Negroes.

Iron deficiency is severe both in patients with total and in patients with partial megaloblastic erythropoiesis, but the vitamin B_{12} deficiency is considerably more severe in patients with total megaloblastic erythropoiesis. As a result patients with total megaloblastic erythropoiesis appear clinically to have pernicious anæmia complicated by iron deficiency, and the usual diagnostic criteria of pernicious anæmia are not obscured thereby, except that there is no initial increase in the serum iron level. Since patients with pernicious anæmia are usually under thorough hæmatological supervision the iron deficiency is nearly always diagnosed, usually when the blood ceases to improve despite continued anti-megaloblastic treatment—a phenomenon well known to clinicians.

With patients who have partial megaloblastic erythropoiesis this is not so. The anæmia presents the characteristics of iron deficiency or other form of simple anæmia and the complicating vitamin B_{12} deficiency may easily escape diagnosis for a very long time. The primary diagnostic difficulties may be seen from tables II and III. There is a negligible difference between the average data for patients with normoblastic (sideropenic) anæmia and patients who also have partial megaloblastic erythropoiesis. The typical effects of the two deficiencies proceed in opposite directions and may neutralise each other in some hæmatological data, which therefore give a false impression, the colour-index and the serum iron, for instance, not being increased (tables II and III). In 1 of our patients (with 55 µµg of vitamin B_{12} per ml. of plasma) the colour index was 0.95 and the serum iron level 46 µµg per 100 ml.; this does not immediately suggest megaloblastic erythropoiesis.

When the mild anæmia has been treated and perhaps partly remedied with, for example, iron, the complicating vitamin-B_{12} deficiency is seldom diagnosed, because such patients are usually not submitted to thorough hæmatological control. This very time, however, would be good for discovering vitamin-B_{12} deficiency because it seems that when one deficiency is relieved another is unmasked. Although perhaps the causal relationship has not been strictly proved, iron therapy seems to promote the signs of deficiency of antimegaloblastic substances. Heath (1932), Miller and Dameshek (1941), and Trowell (1943, 1944) reported cases of pronounced normoblastic iron-deficiency anæmia which bone-marrow studies showed to have become megaloblastic when treated with iron—to the great surprise of the investigators. In obscure cases we have, as mentioned above, systematically used intensive iron therapy to this end and have thereby induced typically megaloblastic erythropoiesis.

Partial is more interesting than total megaloblastic erythropoiesis with iron deficiency because in this condition it is more difficult to diagnose vitamin-B_{12} deficiency and iron deficiency. This difficulty, however, has probably not prevented correct treatment in some cases in spite of an incorrect diagnosis—e.g., when liver therapy has been successful in dealing with the anæmia of achlorhydric patients after iron has proved ineffective.

Since vitamin-B_{12} deficiency is not uncommon in achlorhydric patients with mild anæmia and is often complicated by iron deficiency and/or anæmia of multiple origin, a closer examination of the peripheral blood picture and a more frequent use of sternal bone-marrow are essential if this condition is to be diagnosed more often. Besides, determination of the vitamin-B_{12} content of the blood and repeated examination of the bone-marrow after intensive treatment with iron seem to be important diagnostic procedures.

Vitamin C Deficiency

This condition was found in nearly all the patients in both groups. Since vitamin C increases the uptake of dietary iron (Moore 1955), vitamin C deficiency may be expected to contribute to the iron deficiency. Vitamin-C deficiency may play a part in the development of megaloblastic erythropoiesis because vitamin C takes part in the metabolism of folic acid; but we have not observed any decrease of megaloblastic erythropoiesis or of reticulocytosis after the administration of large doses of ascorbic acid, even though the serum ascorbic-acid level has been brought back to normal by this treatment.

Deficient Diet of Aged Persons with Achlorhydria

Since cancer and hæmorrhage were found only in exceptional cases, the main cause of iron deficiency must be a decrease in absorption and/or administration of iron. The absorption of iron must have been greatly reduced in those patients in whom only intravenous administration could deal with the iron deficiency. But the diet may also have been poor, qualitatively and/or quantitatively. Although a purely nutritional iron deficiency anæmia in men and postmenopausal women is often considered merely a theoretical possibility, a diet which per se is not particularly poor may become so insufficient for an achlorhydric person with little appetite, dyspepsia, and poor absorption that a previously acquired iron deficiency persists. However, the pronounced vitamin C deficiency indicates that the diet would have been faulty even for healthy people, because we have so far seen only 1 patient who could not absorb vitamin C given by mouth. We have found that lonely old people often take incredibly little and of a very poor diet. This agrees with more elaborate geriatric studies (Eckerström and Geill 1955, Lyons and Trulson 1956). It therefore seems probable that the iron deficiency is due not exclusively to a reduced capacity to absorb iron but also to insufficient nutrition. Achlorhydric and other dyspeptic patients—especially elderly women—appear to be particularly exposed to such faulty nutrition.

Possibly some of our cases of vitamin-B_{12} deficiency were partly due to inadequate diet (cf. Harrison et al. 1956). To investigate this question further studies with labelled vitamin B_{12} and gastric biopsies would be necessary.

Summary

Serial studies of the sternal marrow in 46 patients, aged 50 or more, with histamine-refractory achlorhydria and mild anæmia but no manifest pernicious anæmia showed that 7 had partial or incipient megaloblastic erythropoiesis. This incidence agrees with recent studies on the incidence of gastric atrophy and reduced absorption of vitamin B_{12} in achlorhydric people.

Partial megaloblastic erythropoiesis in patients with mild anæmia is too seldom diagnosed because mild vitamin-B_{12} deficiency is often masked by more or less severe iron deficiency (dimorphous anæmia) and vitamin-C deficiency and/or anæmia of a different pathogenesis; hence some ordinary hæmatological studies (colour-index, serum-iron level) may be misleading. Studies of the sternal marrow are therefore of the utmost diagnostic significance. Determination of the vitamin-B_{12} level in the blood may also acquire importance, and it is emphasised that relief of iron deficiency may accelerate the signs of vitamin-B_{12} deficiency in the erythropoiesis.

Two clinical types with partial megaloblastic erythropoiesis are described: one is characterised by incipient ordinary pernicious anæmia complicated by iron-deficiency anæmia, and the other by anæmia of multiple origin.

Treatment with iron and vitamins B_{12} and C is rewarding but has to be intensive and prolonged (this applies particularly to the iron medication) before the blood returns to normal.

As the vitamin-B_{12} level in the blood-plasma falls, we can recognise four categories: (1) apparently healthy people, (2) histamine-refractory achlorhydric people with normoblastic erythropoiesis, (3) partial megaloblastic erythropoiesis, and (4) total megaloblastic erythropoiesis. The transition between the groups appears to be fairly even, as might be expected.

Unlike the vitamin-B_{12} deficiency, the incidence of iron and vitamin-C deficiencies appears to be equal in patients with total and in patients with partial megaloblastic erythropoiesis. Vitamin-C deficiency is due to a faulty diet, and iron deficiency to insufficient absorption and, probably, a poor diet as well.

Elderly achlorhydric people, especially women, probably often receive a diet which is very poor both qualitatively and quantitatively.

TRACHEOTOMY FOR FLAIL CHEST

STANLEY HULMAN
M B Leeds
SURGICAL REGISTRAR, PONTEFRACT AND CASTLEFORD GROUP OF HOSPITALS, YORKS

INJURIES to the thorax, with fracture of one or more ribs or costal cartilages, are very common and are quite simply and satisfactorily treated in most cases, but the crush injury causing multiple fracture of ribs and costal cartilages, producing "stove-in" or "flail" chest, with its paradoxical movement, is surprisingly rare Proctor and London (1955) collected only 8 recorded cases of stove-in chest, with paradoxical respiration requiring surgical treatment in 344,000 injured persons treated at the Birmingham Accident Hospital in 1944–52, only 1 of the 8 patients survived The gravity of this condition and its high mortality are emphasised by many workers—e g, Cameron et al (1949), Coope (1948), Elkin and Cooper (1943), Gardner (1946), Heroy and Eggleston (1951), and Rives and Kahle (1939)

Results of Flail Chest

The pain on breathing limits the respiratory excursion of the chest, and the paradoxical movement of the unstable part of the chest wall reduces still further the tidal volume—i e, the breathing is shallow and inefficient, and aeration of the lungs is poor

More rapid and vigorous respiratory efforts result, involving the accessory muscles of respiration, with accompanying exhaustion and increased pain

There is loss of effective cough, with accumulation in the tracheobronchial tree of secretions which increase the resistance to inspiration and expiration The intrapleural negative pressure on inspiration is greatly increased and on expiration is decreased or may become positive This increases paradoxical movement The deterioration in the patient's condition at this stage is often striking and alarming

Considerable anxiety is caused by a sense of suffocation (Heroy and Eggleston 1951)

Treatment

In the mild case adhesive strapping may suffice, for the more severe injuries most workers suggest skeletal traction applied to the ribs, costal cartilages, or sternum (Bailey and Matheson 1953, Butler 1938, Davis 1956, DeBakey 1942, Dolley and Brewer 1942, Wise 1942)

Jaslow (1946) describes the use of towel clips and screw-hooks Jones and Richardson (1926) the use of cervical forceps, and Proctor and London (1955) the use of cup hooks, applied to the sternum in each case Heroy and Eggleston (1951) used a sharp clamp designed originally for reducing Bennett's fracture Williams (1948) used pericostal traction with towel clips

McKim (1943) treated a case by open operation and reduction of the displacement, inserting Kirschner wires across the fracture sites, and Sweet (1954) advises open operation and fixation of each fracture with stainless steel wire Coleman and Coleman (1950) advise wiring each fracture, sometimes with the addition of an intramedullary peg, in their cases the average number of ribs so treated was 6, but in one case 16 ribs were wired

Belsey (1953) and Bonnin (1951) advise a plaster of paris cuirass to immobilise the floating segment

Hagen (1945) described an interesting case in which he used a Drinker respirator and Brooks (1942) found the Nuffield respirator satisfactory for this purpose Gray (1942) and Watson Jones (1955) also advise the use of a mechanical respirator

In all these instances apparatus is required which may not be at hand and requires careful and continuous surveillance Skeletal traction also entails the risk of infection which it is so important to avoid in this condition Skeletal traction appears to have little effect in preventing the ultimate deformity of the thorax (Jones and Richardson 1926, Proctor and London 1955)

Treatment of flail chest by tracheotomy has been described by Carter and Giuseffi (1953), who have used the method since 1949, and the treatment in the two cases described here was based on their method

In a survey of the indications for tracheotomy in modern medicine and surgery (Pitman and Wilson 1955) flail chest was not mentioned, nor was it included in the discussion on the value of tracheotomy in acutely ill surgical patients by Colvin and Morrison (1953), who emphasise, however, the importance of prophylactic tracheotomy in very ill post operative patients in whom the cough is expected to be ineffective

Rationale of Tracheotomy

1 The tracheobronchial tree can be aspirated easily and quickly by the nurses to remove the secretions which accumulate owing to the lack of effective cough and tend to produce the "wet lung" syndrome described by Brewer et al (1946) The removal of bronchial secretions reduces the resistance to air movements in the tracheobronchial tree and removes the sense of suffocation

Aspiration through the tracheotomy tube is far simpler and less exhausting to the patient than the repeated bronchoscopic aspiration advised by most workers

2 Dead space is reduced by about 60–75 c cm, the volume of the mouth, nose, and pharynx in anæsthetised patients (Guedel and Waters 1928) Carter and Giuseffi (1953), working on necropsy specimens, found the average volume to be 117 c cm, but one would expect the dead space to be less in the living, owing to the tone of the pharyngeal constrictors Tidal volume is much reduced when paradoxical movement of a segment of the thoracic wall takes place, and the reduction in dead space brought about by tracheotomy, and the equivalent increase in *effective* tidal volume, are probably of clinical importance in the efficacy of tracheotomy

3 The resistance to air movements imposed by the upper air passages, chiefly owing to the small cross section area of the glottis, and caused by the turbulence of air currents in the pharynx, nose, and mouth, is removed, hence respiratory movements can take place more freely The range of negative pressure in the thorax between the limits of the respiratory cycle is reduced, and there is thus less tendency for the "floating segment" of the thoracic cage to be sucked in on inspiration and blown out on expiration (Carter and Giuseffi 1951) Clinically this is apparent in the visibly decreased amplitude of the paradoxical movement Again this favours an increased effective tidal volume, with the expenditure of less energy and causing less pain

4 Oxygen consumption is decreased because of the diminished muscular exertion needed to provide satisfactory ventilation

Each of these four factors contribute something to break a vicious circle and to change laboured, rapid, and shallow into easier, deeper, and slower breathing

With the relief of dyspnœa and pain the patient becomes less frightened and can relax and sleep

One must anticipate the complications of hæmothorax, which occurs frequently after chest injuries (Butler 1938) and may become manifest some days after injury (Cato and Norman 1940), and perhaps pneumothorax, either of which will reduce the patient's vital capacity and increase dyspnœa or accelerate its onset

Tracheotomy is easy to effect under local anæsthesia, but the patient has to lie supine and quite still for a few minutes As indicated in case 2, the onset of complications causes dyspnœa and extreme discomfort when the patient is supine For these reasons it is suggested that tracheotomy should be seriously considered in all cases of flail chest immediately on admission

Case-reports

Case 1—A lorry driver, aged 45, was admitted to the Pontefract General Infirmary on March 5, 1955 He had been leaning over the chassis of his tipping lorry doing maintenance work, with the body of the lorry in the raised position, when the hydraulic mechanism failed and the body descended He sustained a crush injury to the thorax and minor abrasions

On examination he had traumatic asphyxia with exophthalmos, hæmorrhages into the conjunctivæ, petechiæ into the facial skin, and paradoxical sternal movement grotesque in its amplitude He was very anxious, restless, and slightly cyanotic and complained of severe pain in his chest His respirations were only slightly increased in rate but were very laboured, involving the accessory muscles of respiration Radiography showed anterior fractures of ribs 2–7 on the right side and clinically there were also fractures of the costal cartilages or separation at the costochondral junctions 2–6 on the left side

Treatment and Progress—Strapping was applied to the front of thorax, but this did little to diminish the paradoxical movement or to ease the pain Penethamate hydriodide ('Estopen') 500,000 units b d was given prophylactically During the night the patient's chest became wet, and by next morning his respirations were 50 a minute, and his inability to cough, due to both pain and lack of tussive force, caused great distress Tracheotomy was done, under local anæsthesia (2% lignocaine), through a vertical incision, the isthmus of the thyroid gland being divided to give access to the second tracheal ring A Jaques's catheter inserted through the tracheotomy tube and attached to an anæsthetic suction pump removed a large amount of slightly bloodstained mucoid secretion from the trachea and main bronchi The patient was at once less distressed He was nursed in an almost sitting position in a steam tent, aspiration being done every fifteen minutes By the next day his respirations had decreased to 30 a minute, and thereafter they remained 24–30 a minute On the following day radiography showed partial collapse of the lower left lobe with elevation of the left diaphragm and slight surgical emphysema 'Alevaire' was then administered as a mist by attaching an oxygen cylinder to a nebuliser containing the detergent liquid This loosened the mucoid secretion and enabled it to be removed by the suction catheter, which was used as often as required The patient remarked on the efficacy of alevaire, and the treatment was given for a few minutes every hour On March 12 the patient was allowed up for bed making, and on March 14 the tracheotomy tube was removed At that time the paradoxical movement had almost ceased, the patient had no pain, and he had been able to expectorate for two or three days despite the presence of the tracheotomy tube He continued to expectorate large quantities of sputum but had a little dyspnœa at night for some time Serial radiographs showed gradual improvement and expansion of the left lower lobe The patient was discharged from hospital on March 22, 1955, to a convalescent hospital and was finally discharged on April 9, 1955

Follow up—Twenty months after the injury he had no disability, no depression of the sternum, and his chest expansion was $2^1/_2$ inches He had returned to his original work

Case 2—An electrician, aged 31, was admitted to the Pontefract General Infirmary on Nov 10, 1956, having been in a head on collision while driving a motor car He had the typical "steering-wheel" injury, with a very obvious paradoxical movement of the anterior part of the upper left chest He was rather shocked, his respirations were 40 a minute, and breathing was very laboured Radiography confirmed the clinical impression that the upper five left ribs were fractured, each at two sites anteriorly It was surprising that there was no damage to the subclavian vessels

Treatment and Progress—Zinc oxide strapping applied to the upper left chest did not improve the paradoxical movement or the pain Ten hours after the injury the patient was very distressed Moist sounds in his chest were audible without the use of a stethoscope There was now much cyanosis, and tracheotomy was done under local anæsthesia with 2% lignocaine The supine position was extremely distressing to the patient and the operation was done with some difficulty because of his restless movements As soon as the tracheotomy tube was inserted, a large amount of bloodstained mucoid secretion was aspirated with the suction catheter The patient was nursed in the sitting position in a steam tent, with intermittent inhalations of alevaire provided through a nebuliser Next day his cyanosis had disappeared, he was breathing easily, and, although paradoxical movement was still present, the excursion of the floating segment was much less Radiography on Nov 12 showed increased shadowing in the lower half of the left lung field and a pneumothorax estimated at 15% On Nov 13 there was an obvious collection of fluid in the left side of the chest, confirmed radiologically, and aspiration through the eighth intercostal space removed 300 ml of almost pure blood Next day a further 450 ml of blood was aspirated, and on the following morning 40 ml. of bloodstained fluid was removed, this latter with some difficulty Radiography on Nov 15 showed the upper half of the left chest to be occupied by pneumothorax and the lower half by collapsed lung and effusion The apex of the lung, however, showed aeration No further aspirations were done, and serial radiographs showed a rapid re-expansion of the lung and absorption of the pneumothorax and the remaining effusion By Nov 23 the paradoxical movement had completely ceased, the respiratory movements were free and painless, and there was good air entry at the left apex More vigorous breathing exercises were begun On Nov 28 the tracheotomy tube was removed without any following discomfort The patient was discharged from hospital on Dec 4 symptomless, with a slight depression of the anterior upper left chest but no other physical signs

At follow up he had no symptoms, a chest expansion of $3^1/_2$ inches, and had started work

Summary

Immediate tracheotomy is advocated for crush injuries of the chest causing flail chest

Physiological arguments, supported by clinical observations, indicate that tracheotomy breaks a vicious circle and produces less paradoxical movement, better pulmonary aeration, less pain, less expenditure of energy and ease in aspiration of the tracheobronchial tree

I wish to thank Mr J A Rhind, under whose care these cases were admitted and who advocated this method of treatment, for permission to publish and for advice and encouragement at all times

ENDOCARDIAL FIBROSIS OF UNKNOWN ORIGIN

JOHN B PENFOLD
M B, Durh
CONSULTANT PATHOLOGIST,
ESSEX COUNTY HOSPITAL, COLCHESTER

ENDOCARDIAL fibrosis can occur in both infants and adults

In infancy, there is gross thickening of both fibrous and elastic elements in the endocardium, with little or no inflammation or involvement of the myocardium The condition is known as fibroelastosis or fœtal endocarditis, and, though its origin is obscure, Still and Boult (1956), using electron microscopy, have recently demonstrated superficial deposition of fibrin

In adults idiopathic endocardial or endomyocardial fibrosis is generally rare, but may be common in Africa (Ball et al 1954) It differs from infantile fibroelastosis in appearance and does not seem to be so well-defined Descriptions vary, but there is usually an increase in fibrous tissue in the endocardium and to a varying extent in the neighbouring myocardium The elastic tissue is ordinarily unaffected, and there is little or no inflammatory reaction

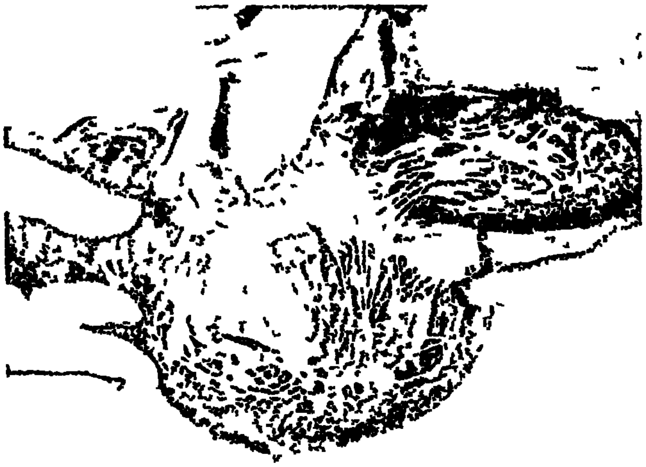

Fig 1—Interior of ventricles showing patchy endocardial fibrosis The myocardium is not involved

In the following case of the adult type, the notable features were the history of possible injury to the heart, the patchiness of the fibrosis, and the absence of elastosis and of involvement of the myocardium

Case-report

Mr A, a journalist aged 67, was admitted in March, 1956 with increasing breathlessness for two months

In 1914, whilst playing cricket abroad, he was hit on the heart ’ by the ball He immediately fell unconscious to the ground and lay there for five minutes Spectators thought he was dead A foreign doctor who saw him diagnosed ‘ concussion of the heart ” and treated him with an electric instrument over the precordium

He served in the Middle East and Gallipoli in the 1914–18 war, and apart from an attack of “ malaria ten years after his return home, he was well until October, 1954 At that time he had a “ strained heart ” and nocturnal frequency, and was admitted to hospital The heart appeared slightly enlarged, pulse rate 84, blood pressure (B.P) 160/95 mm Hg The heart sounds were normal and there was no dyspnœa or œdema Urinary investigations showed an enlarged prostate and a slight left hydronephrosis

In January, 1955, he had another attack of “ heart strain, but he was not admitted to hospital

Last Illness

History—Three months before admission he had become increasingly breathless During the previous three weeks his ankles had swollen and he had had an occasional hæmoptysis, for two days he had been cyanosed and very breathless, and had vomited frequently

He ate a normal diet and had no allergy He had never been to Africa, apart from war service in Egypt

Examination—He was a well nourished man with severe congestive heart-failure He had auricular fibrillation with a ventricular rate of 120 a minute A harsh systolic murmur was heard over the whole cardiac area The apex beat was 5 in from the midline in the 6th space, B P 110/80 A blood count showed a slight polymorphonuclear leucocytosis Total white cell count 14,600 per c mm (polymorphs 82% eosinophils nil)

Congestive heart-failure of unknown origin was diagnosed He died eight days after admission with increasing failure

Necropsy

Nourishment—Good

Cardiovascular ystem—Signs of congestive failure were present The heart was enlarged (weight 405 g), mainly because the ventricles were dilated The aorta and coronary arteries were singularly free of atheroma The pericardium, myocardium, and valves appeared normal, but there were several small mural antemortem thrombi in the right auricle There was a patchy irregular superficial thickening of the endocardium of the left ventricle The myocardium was not involved (fig 1)

A small infarct was found in the lower lobe of the left lung, with an embolus or possibly a thrombus in the appropriate branch of the pulmonary artery There were a few small acute ulcers on the lesser curve of the stomach near the pylorus, with 3 oz of free fresh blood in the lumen An old infarct (2 × 1 × 1 in) was present in the *spleen* Benign enlargement of the *prostate gland*, a large thin-walled *bladder*, and bilateral hydronephroses were found

Histology

There was a thick patchy fibrous deposit in the endocardium containing fine fatty granules, but with little or no proliferation of elastic tissue The myocardium was normal except for some large nuclei (fig 2)

Discussion

Fibrosis of the parietal endocardium of obscure origin can occur in infancy, childhood, and adult life The

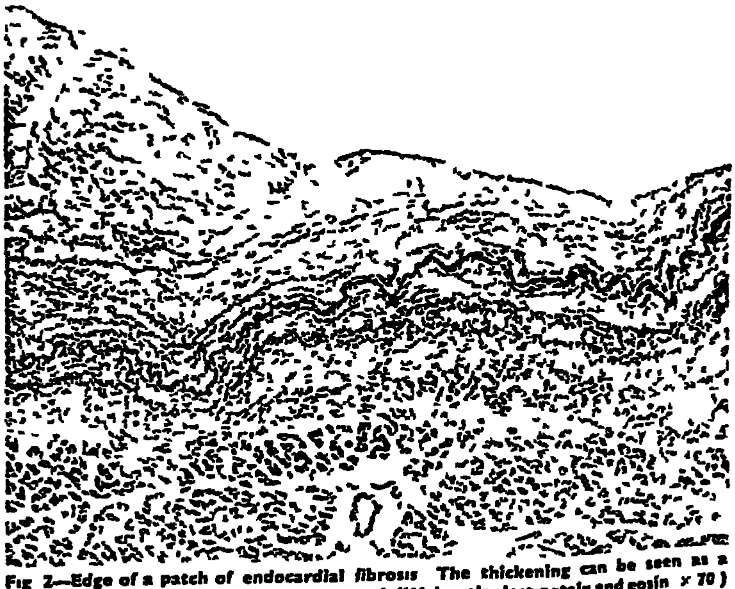

Fig 2—Edge of a patch of endocardial fibrosis The thickening can be seen as a fibrosis as the elastic layer is not increased (Weigert's elastic stain and eosin × 70)

fibroelastosis of infancy is probably distinct from the fibrosis of childhood and adult life, but Thomas et al (1954) suggest that they have a common ætiology. Using Verhoeff's elastic tissue stain they found in their adult cases that the thickening of the endocardium was a fibroelastosis They also tested some of the endocardia from the adult cases reported by Davies and Ball (1955) from Uganda, and found only a few broken elastic fibres, they suggested that each of the two series had a different ætiology The question whether the adult type is a fibrosis or a fibroelastosis is important ætiologically In the case reported here there appeared to be a pure fibrosis of the endocardium, with no increase in elastic tissue and little or no involvement of the myocardium

Despite a long search, no reports of adult endocardial or endomyocardial fibrosis in Britain have been found, but recently Watt and Lynch (1956) described a case of endomyocardial fibroelastosis in a boy of 12 Lennox (1948) reported a case in which a woman had a parietal endocarditis with swollen and pyknotic endothelial cells and infiltration of lymphocytes and polymorphs, the myocardium was œdematous She had status asthmaticus and eosinophilia, and Lennox suggested that the condition might have proceeded to fibrosis had she lived

Adult endocardial and endomyocardial fibrosis though uncommon, has been known for many years, particularly to the German and Swiss pathologists It was reported briefly as early as 1883 (Nauwerk) and at intervals up to 1936—e g, Kockel 1897, Nagayo 1909, Dewitzky 1911–12, Hertel 1921, Boger 1929 In 1936 Loffler described 2 cases as endocarditis parietalis fibroplastica with eosinophilia Since then three large series have been reported from Africa—40 cases by Bedford and Konstam (1946), 40 by Becker et al (1953), and 31 by Davies and Ball (1955), who gave an excellent detailed description of the pathology of the condition On the whole the evidence favours a nutritional cause for the African cases, but Becker et al (1953) suggested it was a collagen disease Gray (1951) described 2 cases in Englishmen living in Nigeria and advanced the idea that as there was no nutritional deficiency in his cases and it was commonest in Africa, it might be due to a tropical infection A similar case in an Englishman resident in Africa who had syphilis was reported by Edge (1946)

Apart from the African series, small numbers have been reported from Switzerland, Germany, Austria (e g, Mumme 1940, Büchler 1941–42, Fossel 1942, Egger 1944, Roulet 1944, Berblinger 1948) and America (e g Comeau 1937, McKusick and Cochran 1952, Smith and Furth 1943, Thomas et al 1954)

The pathological picture in the cases reported is by no means uniform, but a general composite picture can be made up

The patient is usually a man young or middle-aged rather than old (though the condition has been described in a man aged 71) The heart is usually normal in size but it is occasionally enlarged with dilatation of the ventricles rather than hypertrophy Very occasionally the enlargement is massive The pericardium and coronary arteries are normal The mural endocardium is thickened either in a sheet-like manner or in plaques It is usually white or greyish-white The thickness varies but can be up to 4 mm or rarely so great that the lumen of the chamber is largely obliterated The left ventricle is most often affected then the right ventricle, and only occasionally the auricles The commonest site seems to be the posterior wall and the least common the interventricular septum The mitral and tricuspid valves are sometimes involved probably by extension from the walls but the semilunar valves are always free The nature of the thickening is still not clear

The majority of reports describe the condition as a fibrosis others as a fibroelastosis Commonly there is no inflammatory reaction, but in many of the African cases there is a deep layer resembling granulation tissue In the myocardium adjacent to the endocardium there is commonly muscular degeneration and an extension of the fibrosis, more rarely these changes are seen throughout the myocardium In many cases, possibly those of milder type, only the endocardium is affected Inflammatory reaction in the myocardium is uncommon but occasionally small collections of small round cells are seen Polymorphs are noticeably absent

Thrombus formation on the endocardial fibrosis is very common and embolism is rarer than would be expected Other lesions found at different times elsewhere in the body include infarcts, signs of malnutrition allergic and collagen disorders, and eosinophilia in the peripheral blood Loffler (1936) first described the eosinophilia and suggested that it died out as the disease progressed The case presented here showed only some of these features, as do the majority of cases The full picture is rare

The ætiology is obscure, but there have been many suggested causes, such as malnutrition or defective absorption (Smith and Furth 1943), allergy (Loffler 1936, Lennox 1948), Fiedler's myocarditis (Bedford and Konstam 1946), tropical infection (Gray 1951), syphilis or antisyphilitic treatment (Edge 1946), extension of the infantile type to adult life (Thomas et al 1954) collagen disease (Becker et al 1953, Watt and Lynch 1956), pulmonary disease (Lenegre and Gerbaux 1952), stretching of endocardium in cardiac hypertrophy (Hertel 1921), and initial myocardial disease, virus myocarditis, or direct injury (Davies and Ball 1955) It is generally agreed that rheumatism and ischæmia do not cause this disease The only obvious cause in my patient was a presumed injury to the heart, when he was struck in the precordial region by a cricket-ball I should like to advance the view, apparently so far unexpressed, that endocardial fibrosis is the end-result of damage to the endocardium irrespective of the nature of the damage Endomyocardial fibrosis might then be regarded as the final result of more severe damage or as the end stage where both the myocardium and endocardium have been damaged

The nature of the process is still obscure, but if the above hypothesis is accepted, the course of the disease might follow lines similar to those put forward by Duguid (1946, 1949) for the formation of atherosclerosis

Briefly, Duguid's hypothesis is that fibrin deposits are laid down on the arterial intima and that these are incorporated in the intima by organisation with a final covering of endothelium The recent paper by Still and Boult (1956) suggests that a similar process may occur in infantile fibroelastosis

The sequence of events in adult endocardial fibrosis would then be (*a*) damage to the endocardium by one of many possible factors, (*b*) deposition of fibrin on the affected areas, and (*c*) organisation of the thrombi and incorporation in the endocardium as an apparent fibrosis

Summary

A case of adult mural endocardial fibrosis is presented with the necropsy findings Its pathology, ætiology, and nature is discussed It is suggested that it is the end-result of any damage to the endocardium and that the mechanism might accord with Duguid's hypothesis on the formation of atheroma

My thanks are due to Dr S A Propert for permission to publish the case, to Dr P G Seear for details of the patient's history, to Dr L W Proger for his help and advice, and to Dr J W Nicholas for the photograph of the specimen

In acute experimental depletion of potassium the serum-potassium level may show a relationship to the extent of the depletion (Black 1953) In clinical practice, however, *not all depletion arises acutely* *Moreover* a rise in the serum-potassium level at a time of acute loss of potassium has been reported (Moore et al 1955)

We present here the results of 110 simultaneous observations of total exchangeable body-potassium and serum potassium levels in patients with various complaints, mostly either congestive heart failure or steatorrhœa

Methods

The methods used for determining exchangeable body-potassium have been detailed elsewhere (Blainey et al 1954, Flear et al 1957) The serum-potassium levels were determined with the 'Eel' direct reading flame photometer

Results

Table I shows the distribution of the observations and diagnoses Only the patients with congestive heart-failure clinically were œdematous In the accompanying figure the serum potassium levels are plotted against the amounts of total exchangeable potassium in absolute terms and in relation to weight and to height In each case the values are expressed as percentages of the mean normal values computed from published reports (Flear et al 1957)

Discussion

The method used estimates the amount of potassium in the body which has exchanged with its radioactive isotope ^{42}K from twenty four to thirty two hours after its injection Thus total exchangeable mass of potassium (K_e) may be the whole of the body potassium (Corsa et al 1950), but Rundo and Sagild (1955) have considered it to be significantly less They estimated the total body potassium from the total gamma count emitted by the body In people not exposed to radioactive materials this has been attributed solely to the naturally occurring isotope ^{40}K, and the total body-potassium can be computed from the ratio in which ^{40}K is found to ^{39}K Total body-potassium was about 15% more than K_e Theoretically this potassium might be either completely unexchangeable or might exchange at a much slower rate We did not detect any further exchange during the eight hours following the first twenty four after injection of ^{42}K (Flear et al 1957), nor did we detect any further exchange during this period between the body sodium and ^{24}Na, though studies using the longer life isotope ^{22}Na (Veall et al 1955) have revealed a slow further exchange requiring several days for completion Whether a similar slow exchange exists with potassium is unknown However, whichever possibility is correct, K_e probably represents the fraction of body-potassium more readily available for metabolic interchanges

The amount of potassium present in the extracellular fluid of the body constitutes only about 2% of the value obtained for K_e Effectively, then, changes in K_e will reflect changes in intracellular potassium The exchangeable mass of potassium has therefore been used to assess the state of the body-potassium, more particularly the extent of any intracellular depletion Its use is, however, open to certain criticisms Firstly, there is the practical difficulty of the variation in K_e which occurs from individual to individual and from day to day within any individual This variability between individuals to some extent may be mitigated by the separate consideration of males and females and by reference to body weight or to height, on the general principles that the sexes reasonably may be expected to show differences of body content, and that the size of the individual may be a factor involved Sagild (1956) has shown that K_e per kg of body-weight varies with age

Change in K_e may take place from a reduction in the amount of potassium within cells or from a reduction in the number of cells The former constitutes cellular depletion of potassium, and the latter represents loss of tissue mass *Loss of potassium from cells* causes a fall in K_e per kg , whereas loss of lean tissue does not However, these two factors may not be wholly independent It is known, for instance, that experimental depletion of potassium leads to a secondary loss of lean tissue The value of K_e per kg may therefore not fully represent the real depletion of potassium Furthermore, the value for K_e per kg of body weight is altered by change in body composition other than loss of potassium

from cells It cannot, therefore, be relied on by itself to afford a clear index of the normality of intracellular potassium It is necessary also to consider the absolute value for K_e and the value for K_e per cm of body-height

Among changes in body composition influencing the value for K_e per kg may be listed gain or loss of body-fat and gain or loss of extracellular and intracellular fluids in œdematous states and dehydration respectively The qualitative consequence of such changes in composition on K_e (absolute and when referred to body-weight and height) are detailed in table II Such changes in composition may arise singly or in combination Table II focuses attention on the difficulties which arise in interpreting the value for K_e in any one individual, even when all three parameters are used

There is a further complicating factor, at least theoretically possible—i e, the proportion of body-potassium not exchangeable with ^{42}K within twenty-four hours might vary This possibility is raised by the observation reported by Rundo and Sagild (1955) but will not be considered further here

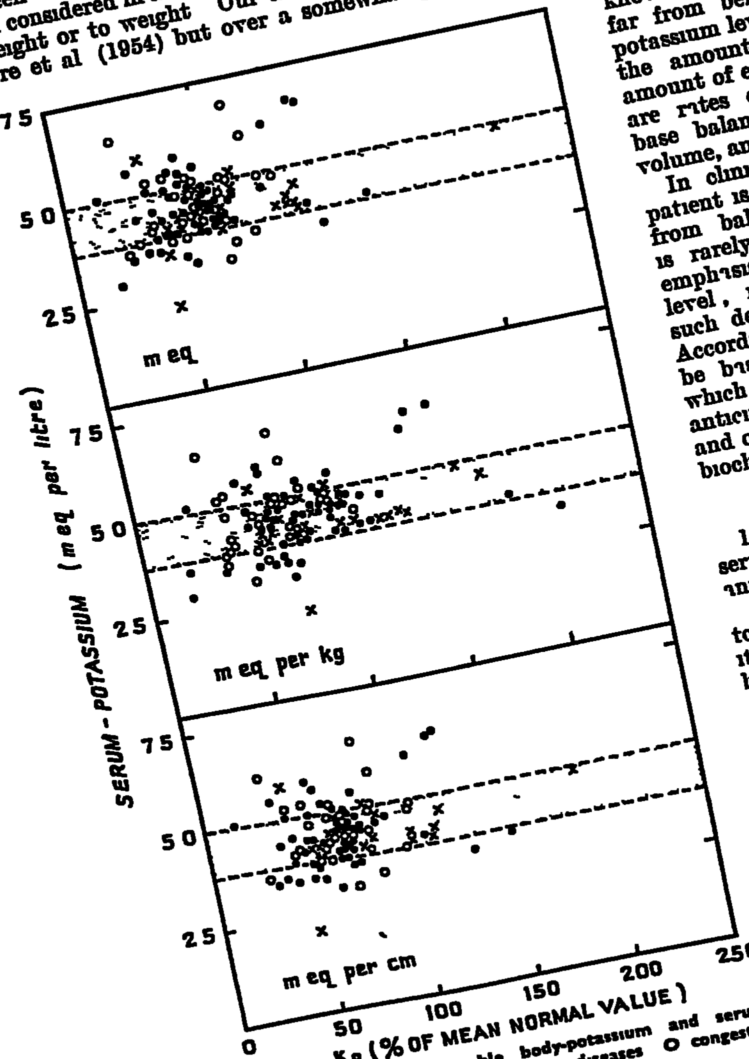
Using K_e as an index of depletion of body-potassium one can say that our data do not reveal any relation between it and the serum potassium level This is so when considered in absolute terms and when standardised to height or to weight Our data thus confirm those of Moore et al (1954) but over a somewhat greater range of variation in K_e (Our range of variation was K_e 16–123%, K_e per kg 27–142%, and K_e per cm 16–123% Their range was K_e 39–101% and K_e per kg 50–102%) The observations of these workers were made on patients with either renal, alimentary-tract, or cardiovascular disease High potassium levels may be found in the presence of low values for K_e showing that such high levels do not imply a normal or raised amount of body-potassium Conversely, a low serum-potassium level need not imply depletion of potassium

TABLE II—EFFECT OF SOME CHANGES IN BODY COMPOSITION ON ABSOLUTE VALUES FOR TOTAL EXCHANGEABLE MASS OF POTASSIUM AND VALUES REFERRED TO HEIGHT AND WEIGHT

Changes in body composition	Changes in total exchangeable mass of potassium		
	m eq	m eq per kg	m eq per cm
Loss of potassium from cells	Decrease	Decrease	Decrease
Gain of intracellular and/or extracellular water—œdema	No change	Decrease	No change
Loss of intracellular and/or extracellular water and salts			
Including potassium	Decrease	No change	Decrease
Excluding potassium	No change	Increase	No change
Loss of lean tissue	Decrease	No change	Decrease
Loss of fat	No change	Increase	No change
Gain of fat	No change	Decrease	No change

These findings are not surprising, because it is well known that the amount of intracellular potassium is far from being a passive consequence of the serum-potassium level Conversely, many factors other than the amount of intracellular potassium influence the amount of extracellular potassium Among these factors are rates of tissue katabolism, renal function, acid/base balance, intake of potassium, extracellular fluid volume, and cellular metabolism

In clinical practice the question whether or not a patient is deficient in potassium often arises Evidence from balance data, muscle biopsy, or radio-isotopes is rarely available Our data clearly indicate that emphasis should not be placed on the serum-potassium level, moreover the symptoms which may accompany such depletion are not pathognomonic and may vary Accordingly the diagnosis of potassium depletion should be based firstly upon a recognition of circumstances which, from experimental and clinical studies, may be anticipated to lead to a loss of potassium from the body, and only secondly upon clinical signs and symptoms and biochemical findings consistent with its presence



Distribution of total exchangeable body-potassium and serum-potassium levels in 110 patients with various diseases O congestive heart failure ●, steatorrhœa X, miscellaneous

Summary

110 observations of exchangeable body-potassium and serum potassium levels are presented which do not show any correlation between them

Clinical awareness of the circumstances likely to lead to potassium depletion is the most important factor in its diagnosis Clinical symptoms and signs and serum-biochemical findings are of secondary importance

We wish to thank the physicians at the Queen Elizabeth and General Hospitals for allowing us to investigate patients under their care, and the ward sisters for their coöperation in these studies

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE

Disorders due to Heat

At a meeting of this society on Feb 21, Dr W S S Ladell, who was recently in charge of the Hot Climates Physiological Research Unit, Lagos, Nigeria, read a paper on Disorders due to Heat

He divided these into four parts skin disorders (sunburn and prickly heat), circulatory disorders (heat syncope), disorders of water and electrolyte metabolism (heat exhaustion, heat cramps), failures of heat regulation (tropical anidrotic asthenia, hyperpyrexia)

Heat exhaustion and heat cramps are probably due to the strain of extra effort in a person chronically slightly short of water At one time salt deficiency was thought to be the major factor, but Ladell now thinks that water debt—in people who consistently do not drink enough—is the predisposing cause Extracellular fluid is lost in the heat, and about 2 litres can be lost before the intracellular water is affected, but the loss of much of the extracellular water renders the person susceptible to heat exhaustion, depletion of intracellular water is dangerous

The rôle of salt is complex In the state of water debt, if water is taken but no salt the intracellular fluid is maintained, and any deficit falls on the extracellular fluid, if salt is taken, particularly in the absence of enough water, the intracellular fluid volume falls, and the extracellular fluid volume is maintained at the expense of the intracellular fluid This intracellular dehydration leads to collapse Treatment consists of plenty of water and a controlled supply of salt, excess of salt will deplete the intracellular fluid and make the patient worse Therefore, in persons in chronic slight water debt, unless there is a sudden emergency calling for an extra output of sweat, extra salt should not be taken, and if any extra salt is taken ample water should be drunk Extra salt may also depress aldosterone secretion, and this may be dangerous Ladell thinks that man has become addicted to salt as a habit, not as a necessity in the amounts normally consumed

Tropical anidrotic asthenia is seen at the end of the hot season, there is no collapse but there is lack of energy, failure to sweat properly, and polyuria The symptoms may be explained first by failure of the renal tubules to respond to antidiuretic hormone, which leads to excessive production of that hormone, and this may suppress sweating Secondly, there is diminished activity by the adrenal cortex, which leads to electrolyte imbalance and asthenia The condition is often associated with prickly heat or lichen tropicalis The only satisfactory treatment is prolonged rest in the cool

Ladell's conception of heat hyperpyrexia is that it is essentially a physiological, not a pathological, process Its ætiology is not clearly known, but it may have an affinity with "sweat gland fatigue" (which, being reversible is not true fatigue) Experiments have shown that the response of the sweat glands in the healthy person becomes progressively less as the rectal temperature rises, and a critical point can be reached (for instance, after hard work in the heat or if physiological cooling is prevented as by the wearing of too much clothing or lack of ventilation) at which sweating stops and cooling ceases with rapid—and without treatment, fatal—results Treatment consists in cooling by means of tepid sponging wrapping the patient in wet towels, and the use of fans for evaporation

Lieut-Colonel J H Walters cited a series of cases of heat hyperpyrexia seen in Iraq and Kuwait Some of the patients were middle aged pilgrims or fat cooks, subject to great heat stress, and some were men with arsenical dermatitis after treatment for syphilis, in the latter sweating was inhibited There may be an element of acute anoxia in heat hyperpyrexia, which may indicate the use of oxygen in treatment In some patients who recovered there was evidence of serious damage to the nervous system

Major-General A Sachs recalled the pathological findings in hyperpyrexia, with hæmorrhages into the suprarenals and cerebellum and circulatory collapse

Reviews of Books

The Nature of Brucellosis

Wesley W Spink, M D, D SC, professor of medicine at the University of Minnesota Minneapolis Minnesota University Press London Oxford University Press 1956 Pp 464 63s

This book gives an up-to-date account of brucella infection ("undulant fever") in man, founded upon a series of 244 cases seen at the University of Minnesota Hospitals

The first part gives a good summary of the history of brucella infection in animals and man, the characters and methods of differentiating the three varieties of brucella, and the natural history of the disease in the animal hosts The author has made a special study of this disease over the past seventeen years, and his cases, each of which he summarises, were thoroughly investigated and carefully treated His handling of the difficult problem of so called "chronic brucellosis" is particularly good, though more attention might have been paid to those cases in which a very short and sometimes afebrile acute attack, which is usually regarded at the time as a "cold," is followed by chronic ill health that is eventually shown by culture or blood agglutination to be due to brucella infection Greater emphasis might have been placed on the value of a negative intradermal test in excluding brucellosis The clinical picture of the Minnesota cases differs considerably (and rather unexpectedly, as they were all due to the abortus variety of the organism) from the English cases reported by Dalrymple Champneys In the Minnesota cases rigors were much commoner, spondylitis was the commonest complication, which was not so in the English series, and unlike the English cases, a majority were occupational infections, 55% of the patients being employed in a local meat packing plant

This is a most valuable work

Modern Trends in Geriatrics

Edited by William Hobson, B SC, M D, D P H, professor of social and industrial medicine, University of Sheffield London Butterworth 1956 Pp 422 72s 6d

This is a welcome addition to British accounts of the care of the elderly Professor Hobson and his eighteen fellow authors have written a textbook with some outstanding merits By careful selection of material, proper emphasis has been placed on aspects where principle and practice differ from those in the care of younger people many of the contributors are not geriatricians but specialists who realise that geriatrics involves problems that concern many different specialties As the title implies, this work is not intended to cover the whole field of geriatric medicine but it could be made the foundation of a reference volume comparable to the well-known American books edited by E J Stieglitz and by A I Lansing

---

Pathological Histology (5th ed Edinburgh F & S Livingstone 1957 Pp 468 32s 6d)—This work by Dr R F Ogilvie has established itself as a standard textbook For the new edition many photomicrographs have been replaced and the text has been rewritten and amplified but the over all length has been reduced

THE LANCET

LONDON SATURDAY, MARCH 2, 1957

Government and Profession

INDIGNATION was justified In the twelve months since National Health Service doctors outlined their case for a rise of pay,[1] the Government had refused to discuss its merits but had kept the negotiations in play Then, without any kind of warning or consultation, they announced that the whole subject of medical and dental remuneration is to go to a Royal Commission—a form of inquiry which takes a very long time Members of our profession who would not wish to press their claim at a moment of special economic difficulty were affronted by a decision which postponed that claim indefinitely and looked as though it were intended to absolve this particular Government of any further responsibility for action—except on the pay of junior hospital doctors Happily the PRIME MINISTER's reply on Monday to SIR RUSSELL BRAIN and DR TALBOT ROGERS' implies that the need for an interim settlement is now recognised

The Government, of course, have their own point of view In this country recovery from the war has not gone far enough to make everyone better off than before, and the attempt to create a more healthy society, without gross poverty, has necessitated a redistribution of real income which has hit many people very hard Among those now less well-to do are most of the professional classes (unless attached to industry), for their earnings have seldom risen enough to make up for the fall in the value of money, and the full force of taxation hits them at a level of purchasing-power which gets lower and lower Responsible elements in both political parties regret the narrowing and impoverishment of professional life thus caused Labour, with its special concern for the success of the nationalised industries and services, should have no wish to drive good brains abroad, while the Conservatives obviously think that redistribution of wealth has gone too far But the remedies, though easy to prescribe, are difficult to apply The three means by which the professional lot could be alleviated are reduction of taxation, increase in pay, and halting of inflation Nobody can doubt that MR MACMILLAN's Government will reduce direct taxation as soon as they dare, but they cannot yet look to much relief on Defence, and meanwhile they have to provide for higher expenditure elsewhere—this year's estimate for the National Health Service, for example, being £49 million more than last year's[2] Though members of some professions could certainly be helped by giving more to those on the public pay-roll, a Chancellor of the Exchequer who wants to reduce taxes is understandably loth to add, for instance, £20 million to the £550 million which taxpayers will have to find for the N H S next year—especially perhaps when he is still under fire for raising only twice that sum by adding 10*d* to the National Insurance contribution Thirdly, a Government can undertake more radical but painful treatment to stop the inflation which is responsible for so many of our symptoms, and if they can show that they are really trying to do this they are entitled to ask for the patient's cooperation Having incurred, to this end, the unpopularity of the credit squeeze, the present Government will naturally be inclined to turn its deafer ear to any small group which is not only asking for a lot of money but also (it may seem) for a privileged economic position

Granted, however, that a Government's duty is to govern—that they deserve no respect unless they can say "No" to their friends—strength of purpose does not excuse unfairness What has been unfair about the attitude of successive Governments is that in seeking economies they have expected a special contribution from people who get their livelihood from public funds When the Civil Servant or the person working in some national undertaking is denied the proper rate for the job because the Government "cannot afford it," he is in fact being forced to make an additional contribution to the Exchequer, supplementary to what he pays in taxes and the same is true of the doctor who is asked to accept uncompensated depreciation of his income when (even in the National Health Service itself) the need for compensation of other groups is freely recognised[3] What is unjust is also in the long run unwise, and grave damage to the service will be averted only if the Government demonstrate that they are not as uninterested or as cynical as they appeared Particularly in a new service such as the N H S, confidence is vitally important, and we trust they will be able to restore it quickly by immediate concessions which reasonable people will find acceptable Thereafter it might be possible for the Royal Commission to plan its work with a view to a fairly early interim report on the general level of medical and dental remuneration and how this should be maintained

What, it is asked, should be the profession's attitude towards the Royal Commission? Apart altogether from delay, two objections to its appointment have been raised First there is the "melting-pot" objection everything (it is rightly said) will have to be considered afresh—from mileage to merit awards—and Spens will be superseded by a report carrying higher authority We admit that in this melting process something may be lost, but we think it at least equally likely that something will be gained—including, possibly, improvements on some of the present methods of remuneration Good though they were, the Spens reports were incomplete and not entirely consistent, and for our part we have long wished to see them reconsidered so that N H S remuneration should be set on a properly agreed base[4] When it comes to the point no responsible inquiry can ignore the terms on which doctors entered the service, and the case for preserving the doctor's accustomed place in the community seems to us so strong that it can safely be entrusted to the judgment of sensible people such as usually sit on Royal Commissions After all at worst, when the commission has reported the profession will be entitled, if it wishes, to hold to the letter of the bargains it reached with the Government in 1946 and 1948. It will be uncommitted by what the commission says. So too, of course, will be the Government; and it is the Government's freedom to pay no attention to the commission's report that is the other big objection raised to the present plan. The outcome here, we believe, depends largely on public opinion. Even among other professional people, the response to the present medical claim has been distinctly ambivalent; and, so far from being thanked for giving a lead, our profession is often held to be taking a selfish line. One reason for this is that, *intent on their present wrongs*, doctors have sometimes seemed to underestimate the difficulties of many other professional people, which may be at least as serious. According to the *Financial Times*,[5] the "average" practitioner with a wife and two children, earning £938 in 1938 and £2222 in 1956, has sustained a loss of real income (after paying taxes) of 27%. But the university professor (arts) runs him close at 24%, and the estimated loss of the headmaster of a large grammar school and of the assistant secretary in the Civil Service are higher at 32% and 43% respectively. As for the general public—many of whom still think that the whole of their weekly National Insurance contribution goes straight into their family physician's pocket—they do not readily understand how doctors justify an average "wage claim" for an additional £10 a week, which is more than many of them earn altogether. They would feel differently perhaps if they saw the calculation[6] that for consultation or visit the doctor now gets an average of half a crown. Perhaps no completely satisfactory arrangements can be made until the public, as well as the Government, understand that they cannot continue to have really good doctors unless they are prepared to pay for really good doctors.

[4] *Ibid*, 1951, i, 1277

But we would add that the future of the profession ultimately depends not on what the public think, or on what the Government say, but on what the profession itself does; and, since the immediate outlook remains uncertain, we must state our opinion of the current proposal that professional action should take the form of pressure on the Government through an undertaking by practitioners to withdraw from the National Health Service. In our view this proposal is wrong: we think that even if it were 100% successful such action would still do great harm to the profession—more harm than could be done by any Government. In offering this opinion we do not mean that doctors need remain in a service in which they lose confidence: we think that those who, now or later, want to leave the N.H.S. should certainly do so; and we agree that if any substantial exodus were in prospect the professional organisations would need to do all they could to help both their members and the public to overcome the difficulties thus arising. But a genuine decision by individual doctors to return to private practice would be quite different from a withdrawal, or the threat of a withdrawal, organised for political ends. This we regard as an alien procedure, out of keeping with the character of any profession, and especially that of medicine.

Hypophosphatasia

IN 1948 RATHBUN[1] drew attention to an osteodystrophy in infants which resembled severe rickets in many respects, but in which there was a great reduction in the level of serum-alkaline-phosphatase activity: he called the syndrome hypophosphatasia. Further reports have appeared of what appears to be the same disorder, and a clearer picture of this remarkable new bone disease is beginning to emerge.

The disorder may be clinically apparent at birth or soon afterwards. RATHBUN's patient was 3 weeks old when first admitted to hospital, with multiple abnormalities and defective mineralisation of the skeleton; and MCCANCE et al.[2] have lately described an infant who was certainly affected at birth and who had indeed been recognised as abnormal in utero by X-ray examination. At birth the bony cranium was very poorly developed and there were widely patent and communicating fontanelles. The chest was flattened at the sides, and beading of the costochondral junctions could be felt. The lower ends of the forearms were much widened, and the long bones were soft and easily bent. An older sister had been shown to have the same condition, from which she had died at 14 weeks. But by no means all cases are apparent as early as this. ENGFELDT and ZETTERSTRÖM's patient[3] seemed to have developed quite satisfactorily until she was 3 months old; then a failure to thrive and the generalised skeletal disorder resembling rickets first became apparent. SOBEL et al.'s patient[4] had evidently progressed well during the first year of life and medical advice was not sought till she was 19 months old. During the preceding 2 months several teeth had been shed, and increasing rickety deformities of the limbs had developed. A similar variation in the age of apparent onset is seen in the three hypophosphatasic children described by SCHLESINGER et al.[5] Two brothers, aged 10 and 13, were admitted to hospital for orthopædic correction of genu valgum and were found to have very low levels of serum alkaline phosphatase[6]; they probably had an even milder form of the condition. When the disease appears in infancy the outstanding features are failure to thrive, early rachitic type bone deformities, and very poor calcification of the skeleton. The fontanelle is often tense and bulging, though the cause of this sign is obscure. The teeth are hypoplastic and are commonly shed prematurely. Very often there is hypercalcæmia and sometimes consequent renal damage. It is possible that these infants are hypersensitive to vitamin D and that even relatively low doses may raise the serum-calcium level.

The prognosis seems poor when the disorder is clearly manifest at birth or soon afterwards, but otherwise it is more hopeful, and the bones slowly calcify, symptoms abate, and growth advances, though varying degrees of bony deformity persist. A surprising complication in some patients is premature craniostenosis which may necessitate cranio

tomy[5] Despite the apparent spontaneous healing, the low serum-alkaline-phosphatase level persists, and this may enable the disease to be diagnosed later in life, when the survivors may be first seen because of skeletal abnormalities and spontaneous fractures[7]

Alkaline-phosphatase activity can normally be demonstrated in serum, and also in many different tissues, especially in calcifying bone, small-intestine mucosa, renal cortex, and lactating breast tissue It seems certain that it plays an important part in normal bone formation but its function in other situations remains obscure Probably several different specific enzymes with alkaline phosphatase activity exist, but they cannot as yet, be identified with confidence In mature bone, phosphatase activity is found mainly in the periosteal and endosteal regions In developing embryos it is found in those condensations of mesenchyme destined to form membranous bones, but not those which will form cartilage and it does not appear in cartilage until just before ossification begins The enzyme activity may be demonstrated in the cartilage cells as they begin to hypertrophy, and it then spreads to the matrix Evidently calcification takes place only in the presence of extracellular phosphatase It has been generally believed that, in bone formation, the enzyme was mainly concerned with the production in the matrix of high concentrations of inorganic phosphate and the consequent precipitation of insoluble calcium phosphate More recent work, however suggests that phosphatase has more to do with the actual formation of the organic matrix[8]

In hypophosphatasia, examination of material from liver, kidney small intestine and bone obtained at necropsy[1,2] and from bone and liver by biopsy,[4] have shown that alkaline-phosphatase activity is deficient in all these tissues It seems that the low serum-alkaline-phosphatase in these patients reflects a generalised defect in the formation of at least one of this group of enzymes throughout the body The abnormal bone development which is characteristic of the disease may be reasonably regarded as a consequence of this failure in enzyme formation, and detailed studies of bone formation in hypophosphatasia may well throw new light on the normal rôle of phosphatase in this process Similarly, we may hope that inquiry into the biochemistry of other tissues in hypophosphatasia will help to explain what phosphatase does in their normal metabolism

One interesting biochemical finding is likely to be significant the urine of patients with hypophosphatasia contains unusually large amounts of phosphoethanolamine,[7,9,10] a phosphate ester widely distributed in the cells of many different tissues[11] Its metabolic rôle is unknown, but the increased amounts in the urine of patients deficient in tissue alkaline-phosphatase suggest that it may be one of the natural substrates for this enzyme[7] and that it accumulates and is excreted in excess when the enzyme is deficient

Hypophosphatasia in more than one member of a family of brothers and sisters is not rare Since no environmental cause has been found to account for this familial incidence, or to explain why only some children in the same family are affected i seems probable that the condition is genetical determined This view is supported by the comm finding that some of the apparently healthy parer and other relatives of affected children have unusually low levels of serum-alkaline-phosphatase[2,4] In at least one instance the parents of the patient were consanguineous[12] The known data are consistent with the hypothesis that the patients with clinically apparent hypophosphatasia are homozygous for a rare abnormal gene, which in heterozygotes results in only minor biochemical abnormalities, leaving the individual clinically unaffected But much more detailed family studies are needed to confirm this hypothesis, and other possible explanations of the familial distribution must be examined Should the genetic hypothesis be confirmed and should the essential metabolic lesion turn out to be defective synthesis of a specific enzyme with alkaline-phosphatase activity then the condition will fall into the classical pattern of an ' inborn error of metabolism '

Annotations

MAN AND RADIATION

In more ways than one, mankind is at an important and possibly decisive point in its history on the one hand, there is the probability, and for Britain the necessity, of a new social and industrial revolution based on nuclear power, on the other, there is the louring threat of a war fought with nuclear weapons and of a hitherto unprecedented and unimagined biological disaster The wider the understanding of what the exploitation of atomic energy can mean (and the dangers it can bring) the more likely is it to be used wisely and the medical profession has a vital part to play in the appreciation of what is happening and in the dissemination of the knowledge necessary for that appreciation

We welcome therefore the statement from the United Nations Scientific Committee on the Effects of Atomic Radiation which we publish on p 467 and which makes several very important points In some countries at least radiological methods now provide the most important source of artificial radiation to which man is exposed In the words of the committee, " irradiation of human beings, and especially of their germinal tissue, has certain undesirable effects ", and artificial irradiation, administered in the course of medical practice, is already, in a few countries at any rate, quantitatively equal to the natural radiation background—a fact which makes plain the gravity of the present situation

The weighing of the balance between the risk and the benefit of medical radiology must remain a responsibility of the medical profession But we know very little about radiation doses and their effects and it is therefore an important duty of every doctor, so far as lies in his power, to cooperate fully with the organisations and the individuals who are at work on these matters, so that all possible information may be sent to the United Nations committee through appropriate Government channels It is already clear that we must urgently seek ways of reducing the radiation dose administered by diagnostic methods without diminishing their efficiency And fuller understanding of the biological action of radiation is necessary for the more accurate assessment of tolerable

exposure levels. There are several difficulties in the study of the effects of low doses of radiation on man: the two main ones are those of measuring in retrospect individual and population dose, and recognising radiobiological effects and correlating them with their true causes. The prevailing uncertainty means constant reassessment and reduction of the recommended "safe" levels of radiation.

In this country machinery now exists, in the form of the committee lately appointed by the Minister of Health under the chairmanship of Lord Adrian,[1] for the collection of relevant information and for reviewing radiological practice. This committee and other bodies, such as the International Commission on Radiological Protection and the Medical Research Council, will be asking for detailed information on radiation dosages and their effects; and we hope they will receive immediate and energetic support from everyone who can help in these crucial inquiries.

LYMPHOGRANULOMA VENEREUM

THE virus infection, lymphogranuloma venereum, which can be a distressing and crippling disease, is fortunately rare in this country and when it appears it is usually in seaport areas. The infection is thought to be imported by coloured immigrants. In recent years there has been an undoubted increase in the number of cases which have been discovered: the chief medical officer of the Ministry of Health reported 63 patients with lymphogranuloma venereum in this country in 1954, and in 1955 the number had increased to 86. The rise in the prevalence of the disease may well have continued in 1956 though no official figures are yet available. It must be remembered too that, from the nature of the disease, particularly in its early stages, many cases remain undiagnosed and are therefore not recorded in the official figures; and it may be that the infection is much commoner than is generally recognised. The recent rise in the figures for lymphogranuloma venereum may be due to the increased entry of Negroes into this country, but there is no proof of this. At all events, it is clear that improvements in present methods of prevention and diagnosis would be welcome.

King et al.[2] examined 1317 patients attending the venereal-diseases clinic at the London Hospital with a view to demonstrating the incidence of lymphogranuloma venereum among this type of patient. After a full clinical history had been taken, the patient was examined and an intradermal test was performed using a yolk-sac culture of the J.H. strain of lymphogranuloma-venereum virus. The sera of all positive skin reactors were then tested for the virus by complement-fixation: fixation of complement at a serum dilution of 1 in 32 or more was regarded as confirmation of the diagnosis. The examinations of 1119 patients were completed. Of the 206 patients (18%) who reacted to the intradermal test, 23 (2%) had strongly positive complement-fixation tests. The sera of 157 (14%) patients reacted in the complement test but not at a level high enough to be taken as diagnostic. Thus, though King et al. believe that 2% of the patients were undoubtedly suffering from lymphogranuloma venereum, 14% presumably required further or longer investigation. Negroes yielded a higher proportion of skin reactors and proven disease than did whites; but there was no evidence to support the suggestion that the recent increase in lymphogranuloma venereum in this country was due to a greater influx of Negroes. Further work on similar lines in different seaport areas seems indicated.

To combat lymphogranuloma venereum, doctors, particularly those practising in and around ports, must be more alert to the possibility of this infection. The opportunity of identifying the transient painless primary lesion is rare, but ulceration of the genital area accompanied by enlarged tender inguinal glands or a bubo should arouse suspicion. The inguinal mass, consisting of many discrete enlarged lymph-nodes held together by a plastic periadenitis, is characteristic and is followed by irregular breakdown of lymph-node tissue, with fistula formation. Suspect cases should be referred to a venereal disease clinic where skin and serological tests can be applied. Further investigation into methods of increasing the specificity and sensitivity of the complement-fixation test for lymphogranuloma venereum might help to determine more precisely the value of the test, and give a clearer picture of the present position.

STABLE SMALLPOX VACCINES

THE dried smallpox vaccines which have now been fully tested under the auspices of the World Health Organisation[1] should do much to improve control of a disease which is still a major menace. In the hot countries chiefly afflicted by smallpox, efficient vaccination has been difficult because ordinary vaccine lymph quickly deteriorates unless kept cool, and the vaccinators seldom have rapid transport or efficient refrigeration at their disposal. Often the population will not come to the large centres where stocks of lymph can be held in refrigerators; and when vaccinators go to the villages, which may be many days' journey from urban centres, their lymph is liable to lose its virtue on the way. For the same reason it may be difficult to hold adequate reserves of lymph at local centres, and the immediate control of epidemics has thus been hampered. But every country can now have dried smallpox vaccine which will withstand many weeks' exposure to tropical temperatures and which will last indefinitely in an ordinary refrigerator working at the usual domestic temperature.

The W.H.O. trials, which started in 1952, were carried out in two stages. The first was a purely laboratory study of the keeping qualities of dried and wet (glycerinated) vaccines produced by laboratories in four different countries. They were tested for heat resistance and bacterial purity in laboratories in Elstree (England), Copenhagen, and Paris after storage at 0°, 22°, 37°, and 45°C for periods varying up to 2 years. The results of these studies have not been published, but by courtesy of W.H.O. it may be said that, though the dried vaccines from all four laboratories were definitely more resistant to heat than the corresponding wet vaccines, there was much variation and one dried vaccine was outstandingly better than the others.

A second batch of this vaccine and another vaccine which had given promising results in a similar study were therefore included in the second stage of the trials. This was a combined field and laboratory study of the two dried vaccines after periods of storage at 37° and 45°C. The dried vaccines selected for this trial were another batch from the laboratory whose vaccine had come out best in the first trial and a vaccine from another laboratory which had given encouraging results in another trial. The dried vaccines were held at 37° and 45°C for periods of 4, 8, 16, 32, and 64 weeks, after which they were tested for potency in the laboratory and for vaccination success rates on volunteers in the Royal Air Force. The laboratory tests were done in duplicate in the department of bacteriology of the University of Liverpool and at the Lister Institute, Elstree, and the potency of all the vaccines was assessed by counting pocks on the membranes of the chick embryo, in addition to the usual test on the skin of the rabbit. The test vaccinations were on groups of 100 recruits with no history of previous vaccination and no scars. For the first time, it was possible to investigate the relative accuracy of the two laboratory methods of test and to assess their relation to success-rates in the field

[2] King, A. J., Barwell, C. F., Catterall, R. D. Brit. J. vener. Dis. 1956, 32, 209.

[1] Cockburn, W. C., Cross, R. M., Downie, A. W., Dumbell, K. R., Kaplan, C., McClean, D., Payne, A. M. M. Bull. World Hlth Org. 1957, 16, 63.

In this trial one dried vaccine resisted heat better than the other The less successful vaccine, however, still produced a 47% vaccination-success rate after 4 weeks at 45°C (a very severe test), 96% successes after 8 weeks at 37°C, and 72% after 16 weeks at 37°C Though the more successful vaccine showed a slight but significant drop in potency after storage at 45°C for 64 weeks, it still produced 100% vaccination successes in the field, as it had at all the earlier tests This indicates that after long exposure in hot climates it would still produce the maximum possible number of successful vaccinations The potency tests revealed the superiority of titration by pock-counting on the membranes of the developing chick -the results obtained by this method showed a satisfactory correlation with the vaccination success rates in the field

On p 446 we publish an article on the heat resistance of a dried smallpox vaccine, prepared at the Lister Institute of Preventive Medicine, which resisted heat very well, as judged both by laboratory titration and by clinical trial We may add that dried vaccine produced by this method has been in use by the Armed Forces for the last two years with uniform success and is also being prepared for the reserves maintained in this country against an epidemic The fact that stable smallpox vaccine is now to be had should enable public-health authorities in hot climates to review their arrangements for the control of smallpox by prophylactic vaccination and to hold reserves of vaccine in many localities for use as soon as smallpox breaks out

DIABETES MELLITUS AND ANÆSTHESIA

IN the preparation of diabetic patients for general anæsthesia, glucose is often given by mouth It is of the greatest importance to prevent both hypoglycæmia and ketosis in these patients, but it is equally imperative not to overlook the potential dangers of *regurgitation* and vomiting when glucose is given shortly before anæsthesia is induced During the past few years, these events have achieved some notoriety as causes of death and other complications in *all* patients given a general anæsthetic, including some with diabetes mellitus

The normal emptying time of the stomach after a solid meal is about four hours, and up to two hours after fluid Thus preoperative oral carbohydrate if it is to serve any useful purpose, must be given so close to the time of anæsthesia that it becomes a potential hazard unless the stomach empties quickly In fact, it may well empty slowly because of fear, premedication, and the glucose itself

King[1] has lately confirmed that the hazard is a real one 200 ml of water, containing phenol red and 50 g glucose, was given to each of a group of fasting healthy young adults and the stomach was completely aspirated at intervals varying from fifteen minutes to two hours It was found that, on the average, the meal was diluted to about twice its volume, but that after two hours only 46 ml of fluid, containing 0 3 g glucose, remained A similar solution, but containing no phenol red was given to each of 20 diabetic and non diabetic patients two hours before operation the stomach was aspirated two hours later Previous investigations had shown that gastric function was normal in all these patients, yet in 10 of them volumes ranging from 100 to 265 ml (average 146 ml), containing 2–10 2 g glucose were removed from the stomach Thus, there seems little doubt that pre operative glucose solutions given by mouth are potentially dangerous and unlikely to prevent hypoglycæmia

The answer is to give the glucose intravenously or not at all A single intravenous injection of glucose given not more than an hour before the induction of anæsthesia may be enough for a minor operation on some diabetic patients, but in most cases King recommends continuous intravenous glucose over a number of hours, including the postoperative period, when there may be nausea and vomiting Soluble insulin should be given in divided doses every four or six hours King believes that this method is the safest and most effective means of ensuring good control for all diabetic patients undergoing emergency or major operations, and for patients with severe diabetes whatever the operation Many mild diabetics need no glucose preparation for a small operation, provided it is carried out early in the morning and an adequate intake of carbohydrate is ensured after operation

King has clarified a subject which is often an irritation to anæsthetists, but he adds a wise reminder that dogma has no place in the control of diabetic patients treated by surgery each case must be considered individually

OPERATING ON EMPHYSEMATOUS BULLÆ

AN emphysematous bulla may become very big and give rise to respiratory distress by compressing adjacent lung If the cause of the trouble is a localised defect of the bronchial tree acting as a check-valve,[1] treatment is straightforward—removal of the affected lobe or segment will liberate the compressed healthy lung and allow it to function But most emphysematous bullæ are associated with generalised respiratory disease, and then the outcome of operation is more problematical These bullæ are usually found in patients with chronic bron chitis, and are merely gross examples of widespread emphysematous lesions caused by air-trapping But routine radiography occasionally discloses large air spaces traversed by filmy strands of tissue in the lungs of people who give no history of respiratory trouble and in whom no evidence of bronchospasm can be detected such lesions may be due to degeneration of the pulmonary elastic tissue and they produce respiratory insufficiency only if the degenerative process extends, if spontaneous pneumothorax occurs, or if air trapping (due to bron chial distortion) causes enlargement of the space with compression of adjacent lung

Surgeons have tried to treat these bullæ in various ways Thoracoplasty has been used in an attempt to obliterate them by external compression, but the results have been poor More success has been claimed for Monaldi drain age[2] (continuous intra cavitatory suction applied by means of a catheter inserted through the chest wall), but this is a laborious procedure involving preliminary pleurodesis to prevent leakage of air or infection from the bulla into the pleural space, and it has won few adherents Resection of the lobe or segment is probably the most widely used operation, and, though it seems undesirable that the remaining part of the lung should have to over expand to fill the hemithorax, Deterling[3] considers that the consequent straightening of the bronchi may bring about a useful improvement in air flow He advises against such space filling measures as plombage, which may have the opposite effect Massie and Welchons[4] point out, however, that resection of a bullous pulmonary unit may entail the sacrifice of functioning lung tissue which can ill be spared, they recommend local excision, even of multiple bullæ, where this will conserve useful lung

Stringer and Burnett[5] now go further and condemn excision altogether They advocate the more economical technique of obliterating the bulla by removing its pleural roof and approximating the pleura and the parenchyma which forms its walls with a continuous suture of fine chromic catgut, each bite including the least possible

depth of parenchyma. This type of operation gave good results in 18 patients, all of whom had obvious respiratory insufficiency due to compression of lung tissue by the emphysematous bullæ themselves or by spontaneous pneumothorax resulting from the rupture of such bullæ. *Postoperative complications* were few: in 2 cases intercostal suction for a fortnight was needed to re-expand the lung, and in a 3rd patient (who had presented as a spontaneous pneumothorax) thoracoplasty had to be performed because the lung did not re-expand fully. There were no deaths, and all the patients, some of whom had been respiratory cripples, were able to return to work. Pulmonary reserve has remained good for periods ranging from six months to four years since operation.

The scope of surgery in the treatment of generalised pulmonary emphysema is severely limited even when the pressure effects of large bullæ contribute significantly to the impairment of respiratory function; but these results indicate that surgery has sometimes much to offer.

ESSENTIAL HYPERTENSION IN CHILDHOOD

THE *measurement of blood pressure in infants and* children is fraught with potential errors. Restlessness or crying may raise the systolic blood-pressure by 20–30 mm. Hg in infants,[1] and a sphygmomanometer cuff that is not wide enough may give readings that are too high. It is also important to recognise the physiological increase in systolic and diastolic pressures which takes place throughout the growth period, so that normal standards may be available[2] against which abnormally high readings may be measured. A persistent reading of more than two standard deviations above the normal for age is generally regarded as representing hypertension.

Hypertension is less common in childhood than it is in adult life, and when it is found it is usually associated with renal disease, coarctation of the aorta, endocrine disturbances, or diseases of the central nervous system. Essential hypertension seems to be rare in childhood,[2 3] but it is a condition which must be considered when the more usual causes of a raised blood pressure have been ruled out. (Clearly, such operable conditions as unilateral renal disease, coarctation of the aorta, and phæochromocytoma must be carefully excluded before a diagnosis of essential hypertension is made.) Haggerty et al.[2] have recently described 9 children under the age of 14 years in whom they made this diagnosis, the youngest being discovered at the age of 7 months. They took as their criterion of hypertension at all ages a blood-pressure which was persistently above 130/90 mm. Hg. In 5 children the blood pressure was more than 160/110 mm. Hg and in all of them headaches and changes in the retinal blood-vessels were present; 2 also had convulsions and hemiplegia, and 1 of them died. Essential hypertension was diagnosed when exhaustive clinical and laboratory investigation failed to reveal any well defined cause for the raised blood pressure; and the search included surgical exploration of the abdomen in all 5 children with serious hypertension. In 5 cases, 4 of them mild, there was a family history of hypertension.

Treatment follows much the same pattern as in adults. Sedation and weight reduction when necessary are important; but restriction of activity and a low sodium diet have not proved practicable in children and they were not therefore adopted by Haggerty. Of the hypotensive drugs, they found rauwolfia, hydrallazine hydrochloride ('Apresoline'), and hexamethonium were all of some value in the milder cases. For the treatment of hypertensive encephalopathy, they were impressed by the efficacy of the ganglion-blocking agent trimetaphan camphorsulphonate ('Arfonad'). In 4 of the most severely affected children, sympathectomy was carried out, with benefit to 2 of them.

Though permanent elevation of the blood pressure is rare in children, a transient rise is quite common. The significance of this finding is not fully understood, but there is some evidence to suggest that children whose blood-pressure behaves in this way may develop essential hypertension in adult life.[3] Hines[4] studied 1522 adults, who were divided into two groups and re-examined ten and twenty years after they had first had their blood pressures measured. Of those in whom the initial reading was 140/85 mm. Hg or less only just under 4% had persistent hypertension twenty years later; on the other hand, in a similar group in whom the first reading was over 140/85 mm. Hg as many as 82% had persistent hypertension twenty years later. Levy et al.[5] found similar but less striking differences among some army officers in a five-year follow-up. Thus, children who show transient rises in blood pressure may grow into adults with essential hypertension; but further investigation is needed before such a conclusion can be drawn.

DISLOCATIONS OF THE LUNATE

INJURIES of the carpal bones are not uncommon but they often escape detection. The increasing awareness of the difficulties in the diagnosis of the scaphoid fracture has not, on the whole, been accompanied by better recognition of the more extensive injuries of the scaphoid and lunate. Provided the possibility of a carpal dislocation is borne in mind, its diagnosis from standard wrist films should present no difficulty.

It is customary to separate injuries about the lunate into two groups—dislocation of the bone and dislocation of the carpus about it. Dislocation of the carpus is commonly associated with a scaphoid fracture, and injuries of the radial and ulnar styloids may also be present. A simple dislocation of the lunate in the early stages can almost always be reduced by local pressure over the lunate, assisted by traction on the fingers, at first in extension of the wrist, and then in flexion. The results of this manœuvre are good, and aseptic necrosis rarely follows. Operative reduction, on the other hand, is seldom satisfactory, and it is probably better to excise the lunate, though the wrist may not recover full function. A recent perilunar dislocation of the carpus, if the scaphoid is not fractured, can also be reduced manually, and if this fails, open reduction gives a fair result. When the injury is associated with a scaphoid fracture, however, the problem is much more difficult. If adequate reduction of the fracture-dislocation can be achieved, then the scaphoid may well unite, although immobilisation for five or six months is often necessary, and the incidence of avascular necrosis of the proximal fragment of the scaphoid may be as high as 50%.[6] Excision of the avascular proximal fragment of the scaphoid allows partial dislocation of the capitate and produces a very poor wrist. It is for these patients, and for those in whom accurate reduction is not possible, that Wagner[7] favours immediate wrist fusion. Such an approach may well shorten the total period of disability.

THE RESPONSIBILITIES OF THE MEDICAL PROFESSION IN THE USE OF X RAYS AND OTHER IONISING RADIATION

Statement by the United Nations Scientific Committee on the Effects of Atomic Radiation

I INTRODUCTION

(1) The United Nations General Assembly, being aware of the problems in public health that are created by the developments of atomic energy, established a Scientific Committee on the Effects of Atomic Radiation This committee has considered that one of its most urgent tasks was to collect as much information as possible on the amount of radiation to which man is exposed today, and on the effects of this radiation Since it has become evident that radiation due to diagnostic radiology and to radiotherapy constitutes a substantial proportion of the total radiation received by the human race, the committee considers it desirable to draw attention to information that has been obtained on this subject

(2) Modern medicine has contributed to the control of many diseases and has substantially prolonged the span of human life These results have depended in part on the use of radiation in ,the detection, diagnosis, and treatment of disease There are, however, few examples of scientific progress that are not attended by some disadvantages, however slight It is desirable therefore to review objectively the possible present or future consequences of increased irradiation of populations which result from these medical applications of radiation

II GENERAL SURVEY OF THE IRRADIATION OF HUMAN BEINGS

(3) Man has always been exposed to some irradiation from natural sources To this has now been added, as a result of modern discoveries and the applications of ionising radiation and radioactivity, certain forms of artificial irradiation

(4) *Natural irradiation* is due to

(1) Cosmic radiation,
(2) " Background gamma radiation from radioactive substances present locally in the earth, rock, or building materials, and from disintegration products of radon in air,
(3) Radiations emitted from natural radio elements such as potassium 40, radium, radon, and carbon 14 which are incorporated in the body

(5) The amount of this natural radiation varies with locality, but has been estimated as usually delivering between 70 and 170 mrems per year to the gonads Of this total, the major contributions are of about 45% from local gamma radiations, 30% from cosmic rays, and 20% from body potassium 40[1]

(6) *Artificial irradiation* is derived from

(1) The contamination of the environment, the atmosphere or water by radioactive waste from atomic industries or from users of radio elements
(2) The radioactive fall out, at greater or lesser distances from the source, or radioactivity resulting from the explosion of nuclear devices
(3) The occupational exposure of certain groups of workers medical practitioners, radiologists, dentists, nurses, atomic energy workers, uranium or thorium miners and the industrial or scientific users of radiation generators or radioactive isotopes
(4) The medical use of X rays, other ionising radiations, and radio elements in the detection diagnosis, investigation, and treatment of human diseases,
(5) The use of certain devices which emit radiation, such as television receivers, watches with luminous dials, and the X ray generators used for the purpose of fitting shoes

(7) The amount of artificial radiation must vary considerably in different countries and we have inadequate information as to the over all significance of these factors In certain countries where estimates have been made, it appears that the greatest gonad irradiation of the population is due to diagnostic radiological procedures, the amount from this source about equalling that from all natural sources in certain instances The total present contribution from occupational exposure, from the products of atomic industries, from radiotherapy, and from the radiating devices mentioned above (paragraph 6, sub-paragraph 5) is likely to be very considerably smaller That from radioactive fall out to the gonads appears at present to be in the region of 1% of the natural gonad irradiation in most areas[2]

(8) Both the magnitude and the significance of these various sources are under review by the committee Since medical irradiation accounts for a substantial if not the major proportion of all artificial exposure, it is important that its magnitude should be known accurately for different countries and circumstances The possibility of making such an assessment depends upon the help of the medical profession, and particularly on the adequacy and availability of records kept by doctors, dentists, and organisations responsible for the use of ionising radiation

III RADIATION HAZARDS

(9) The medical use of radiation is clearly of the utmost value in the prevention, diagnosis, investigation, and treatment of human disease, but the possible effects of this irradiation of individuals require examination

(10) Generally speaking, the irradiation of living beings may produce radiobiological effects either on the irradiated individual himself or, through him, on his descendants , the former being termed somatic and the latter genetic effects Somatic effects vary according to the different organs or tissues affected, and range from slight and reversible disturbances such as cutaneous erythema to the induction of leukæmia or of other malignant diseases The possible reversibility of the somatic effects of radiation received in small doses or at low dose rates encourages the belief that there are permissible doses of radiation which will not cause completely irreversible or significant somatic damage The threshold for occasional somatic damage may, however, prove to be low In the case of genetic effects, on the other hand, there may be no threshold These effects increase with a frequency corresponding to the total amount of radiation received by the germinal tissues, and in the great majority of cases, are adverse

(11) Many other factors complicate the interpretation of radiobiological effects The differences between whole and partial body radiation, between a single exposure and continuous irradiation, or between the effects of different types of radiation are still imperfectly understood Biological differences in the radiosensitivity of various tissues, or of the tissues of people of different age or sex, obviously influence the nature of radiation hazards It is clear, however, that any radiation of gonads, and any substantial irradiation of other tissues, involve a chance of significant damage which requires assessment

IV GENERAL RECOMMENDATIONS REGARDING THE MEDICAL AND OCCUPATIONAL IRRADIATION OF HUMAN BEINGS

(12) The radiological profession, through the International Commission on Radiological Protection,[3] has

---

[1] From reports sent by India Sweden the United Kingdom, and the United States of America

[2] According to the reports sent by the United Kingdom and the United States of America

[3] Report of the International Commission on Radiological Protection. *Brit J Radiol* December, 1954, suppl no 6 *J franç electro radiol* October, 1955, no 10, &c

undertaken a valuable and responsible duty in defining maximum permissible limits of exposure for the main radiation hazards

(13) The establishment of these maximum permissible levels for those who are occupationally exposed to radiation depends on the view that there are doses which, in the light of our present knowledge, do not cause detectable somatic injury in the individual irradiated, and on the consideration that the number of individuals concerned is small enough for the genetic effects on the whole population to be negligible For the gonads, or for irradiation of the whole body, the levels are such as to exclude doses greater than 0 3 rem in any week or 3 0 rem in any 13 weeks, or a sustained irradiation rate greater than 5 rem per year These values imply that no total dose of over 50 rem will have been received by the gonads by the age of 30, or of over 200 rem by the whole body by the age of 60, in any occupationally exposed person [3]

As regards irradiation of the whole population, it is considered prudent to limit the average dose to germinal tissues from artificial sources to the order of magnitude of that received from all natural sources

(14) In considering the extent to which the population is irradiated for medical purposes, it is essentially the genetic hazard which is involved although it seems possible that in certain circumstances somatic injury may occur occasionally after low doses of radiation arise Otherwise, the relevant dose is that indicating the mean gonad irradiation among the population as a whole up to the end of the average reproductive period

(15) The extent of such genetic irradiation from diagnostic procedures has been found to be equal to at least 100% of all natural radiation in two countries,[4] and that from a third equalled at least 22% of this figure [5] Even before obtaining more exact values for these and other countries, it is clear that the exposure can be substantial in countries with extensive medical facilities, and that it is essential to consider any ways in which this exposure could be reduced without detriment to the existing or developing value of medical radiology

(16) The committee is therefore anxious to obtain the help of radiologists in suggesting through appropriate governmental channels any methods by which this total exposure could be reduced and in estimating the amount of reduction that might be expected from any such methods In particular it would be valuable to know how much the radiation to the gonads could be reduced

(a) by improved design or shielding of equipment,
(b) by fuller training of any individuals using radiographic or fluoroscopic equipment,
(c) by any local shielding of the gonads that is practicable, especially during abdominal or pelvic examination,
(d) by the use of techniques involving radiography rather than fluoroscopy when full information can be obtained by this means,
(e) by improvement of administrative arrangements designed to obviate unnecessary repetition of identical examinations of the same subject,
(f) by a general study of certain medical conditions such as that of peptic ulcers to identify the circumstances in which the establishment of a radiological diagnosis has or has not a definite influence upon the treatment or prognosis given

V SUMMARY

(1) The Scientific Committee on the Effects of Atomic Radiation established by the United Nations General Assembly accepts the view that the irradiation of human beings, and especially of their germinal tissue, has certain undesirable effects

(2) Information received so far indicates that, in certain countries (Sweden, United Kingdom, United States of America), by far the most important artificial source of such irradiation is the use of radiological methods of diagnosis and that this may be equal in importance to radiation from all natural sources It is possible that such radiation may be having a significant genetic effect on the population as a whole

(3) The committee is fully aware of the importance and value of the medical use of radiations but wishes to draw the attention of the medical profession to these facts and to the need for a more accurate estimate of the amount of exposure from this source The help of the medical profession would be most valuable to make it possible to obtain fuller information on this subject

(4) The committee would be particularly grateful for information through appropriate governmental channels on ways in which the medical irradiation of the population can be reduced without diminishing the true value of radiology in diagnosis or treatment

MALTA MEDICINE

EARLY last year a dispute arose between the government of Malta and the Medical Officers' Union As part of the settlement of this dispute a commission was appointed to review the medical services of Malta and Gozo and make recommendations for their future organisation Mr John Cronin, M P, had previously submitted a short report on the services [1] The chairman of the commission was Mr Leslie Farrer-Brown, director of the Nuffield Foundation, who was nominated by the Colonial Secretary The other members were Sir Harold Boldero and Mr J Bagot Oldham, nominated respectively by the Royal Colleges of Physicians and Surgeons They have now made their report,[2] in which they endorse the view that "Malta is midway in the modernisation of its medical and health service"

The report commends the progress already made, but says that much remains to be done Development has so far been piecemeal with no general plan There is still much suspicion and ill-will between the government and the doctors, and the commission hopes that the government will set about healing the breach by giving a clear indication of its good intentions The following is a summary of the findings and advice given in the report

ADMINISTRATION

At present the health services are controlled by the minister of health, the chief government medical officer, the senior medical officer (who is in charge of hospital and specialist services, district medical services, and the School for Nurses), and the senior health officer (who is in charge of public health services) There are certain statutory bodies such as the Council of Health (which recommends legislation and investigations), the Medical Board (which has various duties including the issue of licences to practise), and the Board of the Hospital for Mental Diseases (which is concerned with certifying insane persons but not with administering the hospital), as well as the non statutory Hospital Board, which was formed in 1935 to advise on the running of the hospitals, has met few times, and is regarded as a failure

Comment —Control is over centralised and the senior officers have not enough staff There is no established machinery for consultation between government and doctors The disciplinary machinery is faulty The implied distinction between medicine and health is unfortunate

Proposals —Three bodies should be created

(1) A Medical Council, with functions similar to those of the General Medical Council in Britain The chairman would be a judge and the members include some appointed

---

[1] See *Lancet* 1956 ii 1271
[2] Farrer Brown L Boldero H Oldham J B Report of the Medical Services Commission London 1957

by the government and the university and some elected by doctors and dentists.

(2) An Advisory and Executive Board, whose members would be in part appointed by the government and the hospital management committees and in part elected by doctors and nurses. It would advise the Minister on various topics, keep a register of professions, and review the terms of service of medical appointments. It should have several standing committees.

(3) Four hospital management committees, to ease the administrative load on the headquarters staff and improve the running of the hospitals. On each about a third should be active staff in the hospitals and a third laymen, with a lay chairman. The mental hospitals in Malta and Gozo would come under one committee and all other hospitals in Gozo under another, which could with advantage be made the standing committee for Gozo on the Advisory and Executive Board.

HOSPITALS

The existing hospitals are reviewed in detail.

St Luke's is the main general hospital with over 500 beds, and there is room for expansion in the present buildings. It has consultants in various specialties, and the physician, surgeon, and accoucheur are professors in the university. There are three anæsthetists, often one is working in two operating theatres simultaneously. There is a large but ill-equipped and ill staffed laboratory. The female nurses are controlled by a mother superior and the male nurses by a wardmaster, neither of whom is State registered. Most ward-sisters are State registered and most nursing is done by hospital attendants.

The Central Hospital has a few beds for venereal disease, dermatology, and ophthalmology, most of it is used as a police headquarters. There are an ophthalmic clinic, which is too small, and antiquated radiotherapy apparatus. The other hospitals house mental patients, the infirm and chronic sick, the diminishing number of lepers, and patients with tuberculosis, tinea capitis, and infectious diseases.

In Gozo is an adequate general hospital of 94 beds, a mental hospital, and a home for the infirm.

Comments and Proposals.—The basic specialties are well established, but there are no units for such sub-specialties as neurology or plastic surgery. Such units are not needed, in view of arrangements with hospitals abroad and the possibility of each of the present consultants developing a special interest.

More and better accommodation is required for the chronic sick, with more segregation—e.g., the young from the old. More doctors, and especially more administrative assistants, are wanted. All the hospitals were spotlessly clean, but on the whole cheerless and ill-provided with amenities. The internal and external surroundings should be made more cheerful and occupational therapy should be provided.

There is little or no shortage of beds, but more consultants, more residents, and many more nurses, technicians, and clerks are needed. Some consultants seem to have insufficient qualifications and experience, and either a scheme for much more postgraduate teaching overseas should be started at once, or the conditions should be improved enough to attract trained specialists from abroad. Selected laboratory assistants should also be sent abroad for training.

Each medical superintendent should be responsible to the hospital management committee, and in St Luke's Hospital his load of responsibility should be shared by a medical staff committee including all the consultants. There should be a lay secretary and a fully qualified matron, and a records officer trained in Britain.

More beds (including an admission block for men) are urgently needed at the mental hospital, and new accommodation at St Luke's is needed for the units now at the Central and isolation hospitals. But there is no need for a new general hospital, for St Luke's would be big enough if fuller use was made of existing beds. The only waiting lists are a short one for ear, nose, and throat cases and one for minor surgical cases. The demand for children's beds is generally falling and home care schemes would help to reduce it even further.

NURSING

Working on the two islands are 87 State registered nurses, and 646 hospital attendants most of whom have had no proper training. There is a school for nurses at St Luke's Hospital, but very few apply for training. This is partly because nursing as a profession is not held high in public esteem and partly because conditions and pay for student nurses are poor, especially compared with those of hospital attendants. A proposed training-course for attendants has been delayed because of a dispute over lecture fees.

Most ward sisters are members of the order of Sisters of Charity, to whom Malta "has reason to be grateful." But few are State registered, though the mother provincial of the order intends to send more to Britain for training.

Recommendations.—Every hospital should have a matron who is a State registered nurse and who must be an equal partner with the medical superintendent. She should be responsible for the nursing and welfare of patients, for the recruitment, training, and welfare of nurses, and for ward equipment, but not for catering. There should be higher pay for students and State registered nurses and a fully residential school, and the present ward sisters should be encouraged to train for State registration.

DISTRICT SERVICES

Malta is divided into three areas, each with its medical officer of health. He has a staff of sanitary inspectors and health visitors. There is a public-health laboratory and antenatal, child-health, school, and tuberculosis services. The district nursing is done by a small voluntary organisation.

Proposals.—The responsibilities of the M.O.H. should be enlarged and he should be given clerical help and an assistant chief sanitary inspector. The health visitors need better training. The obstetric services should be more unified. The family doctor who is to conduct the delivery should give antenatal care, and the antenatal clinics be replaced by consultative clinics staffed by obstetric specialists. Similarly, hospital and district care for babies and children should be part of one comprehensive service, whose staff should consist in family doctors rather than full time clinic officers. The care of mentally deficient children needs great expansion.

A campaign to make the public aware of the importance of dental health should be begun. As it succeeds more dentists will be needed.

The government should grant the district nursing association enough money to expand its services to cover the island. The industrial health service should be part of the general medical service.

At present, prescriptions for free drugs for the needy are scrutinised centrally with much delay. This scrutiny should be abolished or made locally.

INSURANCE CERTIFICATION AND NEEDY PATIENTS

Whole time doctors are employed to investigate claims under the National Insurance Act. There is little justification for this unsatisfactory system, and certificates from the doctor treating the patient should be accepted.

Few patients pay hospital fees, and even fewer pay the maximum fees, but even these do not cover the cost of treatment. The needy can also get aid for drugs, appliances, special diets, &c., and there are district medical officers to care for them. This last system is unsatisfactory in many ways, not least because the patient has no choice of doctor. Poor patients should be allowed to consult a family doctor in the ordinary way, and he should be paid by the government for such services—preferably on a capitation rather than a fee for service basis. The present district medical officers hold pension rights which would have to be honoured.

TERMS OF EMPLOYMENT OF DOCTORS

The present arrangements are full of anomalies The doctors in government service should be divided into

(*a*) Professional Civil Servants, including the chief government medical officer (whose salary should be £2000 a year, i e , the equal of the highest ranking Civil Servant), medical officers of health, and port medical officers

(*b*) Clinicians having no relationship to the Civil Service

The appointments of the clinicians should be whole-time (without private practice), or part-time and paid on a sessional basis

Those holding conjoint posts (with government and university) would be reckoned as part time clinicians Specialist posts should carry superannuation rights The payment recommended for each weekly session is £175 per annum for the senior consultants and £120–170, according to seniority, for the other consultants A medical superintendent engaged mainly in administration should be paid £1250 and given free board and lodging The junior posts would carry proportionately smaller salaries

There should be scholarships for study abroad free from any legal restriction about future service

---

THE PRIME MINISTER TO THE NEGOTIATING COMMITTEE

On Feb 26 the Prime Minister published his reply to a letter sent to him by Sir Russell Brain and Dr A Talbot Rogers, joint chairmen of the Negotiating Committee, in which they expressed the committee's dissatisfaction at the Government's decision to appoint a Royal Commission to consider the profession's remuneration claim In the committee's view

"The Government has refused to honour its obligation to apply the terms of the Spens Committee's reports, as interpreted by the Danckwerts award It has thus broken its agreement with the doctors when they entered the health service It has been made clear that the Government does not recognise this obligation, but the late Minister of Health, Mr Turton, said that it would not be right for him to be judge in his own cause"

The committee agreed, however, that the method of adjusting medical remuneration to changing circumstances might usefully be considered They added

"If that stood by itself we should welcome the opportunity of assisting the Government in every way possible But a Royal Commission is no answer to the present claim, and it is manifestly unfair that doctors who have had no compensation for the rise in the cost-of-living for six years should await the result of the slow deliberations of a Royal Commission, and meanwhile be expected to go on loyally and ungrudgingly maintaining the health service though their real incomes remain grievously depressed We therefore ask that the present dispute between us should be submitted to an independent arbitrator without delay"

The text of the Prime Minister's reply is as follows

"Dear Sir Russell Brain I have to acknowledge the letter of February 21 signed by yourself and Dr Talbot Rogers regarding the difficult situation that has arisen in connexion with the remuneration of doctors in the health service

"Naturally I am very sorry that it has not been possible to arrive at an agreed solution of this problem The Government feels that the Royal Commission is the only way in which a permanent system can be devised which will stand the test of time I want to assure you that the purpose of the Royal Commission is not to waste time On the contrary, I shall certainly urge its chairman to proceed without delay Moreover, the work of the Royal Commission would not preclude some interim adjustment

"I must also repeat the Government's offer to deal with certain classes, that is hospital officers up to senior registrars, immediately

"While I realize the disappointment of your members at any delay I am convinced that in the long run this procedure is likely to improve the relations of the medical profession with the State and the public whom they serve so loyally"

CENTRAL PUBLIC HEALTH LABORATORY, LONDON

The investigation reported here is concerned with some of the facts known about poliomyelitis patients in households where there have been 2 or more cases The data relate to all such cases notified in England and Wales during the years 1951–54 Similar studies have been published abroad, but no comparable figures have appeared for this country

TABLE I—DISTRIBUTION OF MULTIPLE CASES OF POLIOMYELITIS IN HOUSEHOLDS

No of cases in household	No of households			
	Paralytic cases only	Non paralytic cases only	Paralytic and non paralytic cases	All cases
1	7603	3731	0	11,334
2	72	72	88	232
3	3	8	15*	26
4	0	2	1†	3
Total	7678	3813	104	11,595

* 6 households with 2 paralytic cases and 9 with 2 non paralytic case
† 2 paralytic and 2 non paralytic cases

MATERIAL AND METHOD

The information used was available from an investigation (Medical Research Council 1956) on inoculation procedures and neurological lesions, and comprised records of cases of poliomyelitis notified between April 1, 1951, and Dec 31, 1954 Cards existed for each patient giving the following information (*a*) age and sex, (*b*) whether paralytic or non-paralytic, (*c*) date of onset of illness, (*d*) address, and (*e*) history of tonsillectomy or inoculation within twelve weeks of onset

These records were examined to identify all cards which showed the same address All cards that related

TABLE II—AGE AND SEX DISTRIBUTION OF PRIMARY AND SECONDARY CASES OF POLIOMYELITIS IN HOUSEHOLDS WHERE MULTIPLE CASES HAVE ARISEN PRIMARY CASES INCLUDE ALL DOUBLE PRIMARIES WITH ONSETS ON THE SAME DAY

Age (yr)	Primary cases			Secondary cases			All multiple cases		
	Male	Female	Total	Male	Female	Total	Male	Female	Total
0–5	66	60	126	36	46	82	102	106	208
6–10	61	26	87	39	24	63	100	50	150
11–15	16	10	26	15	17	32	31	27	58
16–20	7	7	14	8	8	16	15	15	30
> 20	22	23	45	24	35	59	46	58	104
	172	126	298	122	130	252	294	256	550

to institutions such as schools, barracks, and places other than ordinary households—about 10% in all—were then eliminated. The remaining cards were taken to refer to individual households. This process may appear rather arbitrary, but there was in fact little difficulty in classifying the institutional cases, and the remainder were nearly all people of the same name living at the same address.

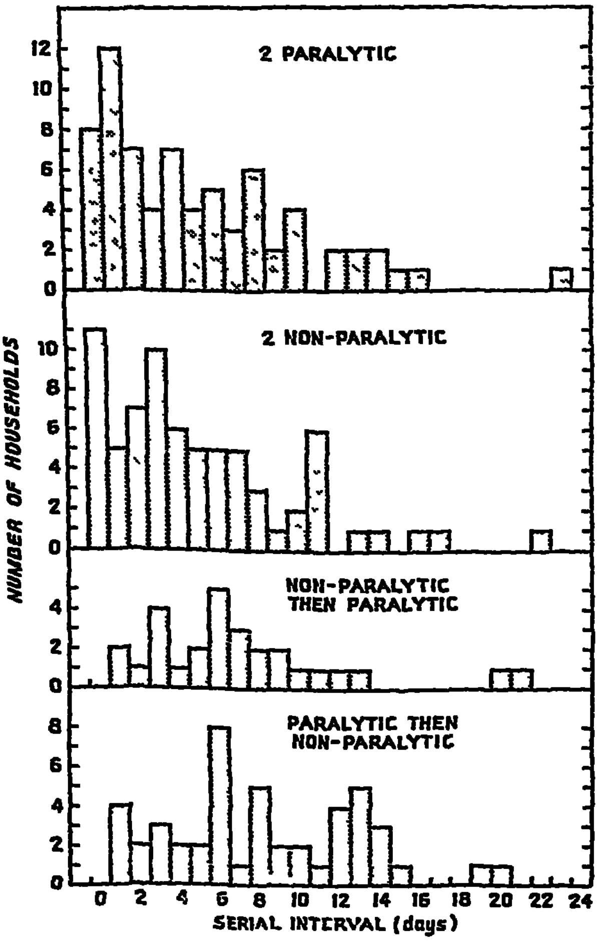
The records were complete in almost every instance, but in one or two the exact age was not given or the date of notification was given instead of the date of onset. There were 5 households in which the dates of onset of illness were more than sixty days apart; these were excluded from further study.

RESULTS

Household Distribution

Table I shows the number of households with various numbers of paralytic and non-paralytic cases. The number of households with single cases is slightly overestimated, since multiple cases in institutions were eliminated but single cases were not.

The proportion of households with multiple cases was about 2·3%—rather less than the 3·6% reported by Siegel and Greenberg (1953) for New York. In only 82 out of 7782 households in which there was a patient with paralytic poliomyelitis was there a second paralytic case. The difference between the numbers for houses with paralytic cases only, and for those which included non-paralytic cases, is not unexpected, in view of the uncertainties of diagnosis of non-paralytic poliomyelitis and the lesser likelihood of it being notified.



Distribution of serial intervals in households with 2 cases of poliomyelitis classified according to type of cases.

TABLE III—DISTRIBUTION OF SERIAL INTERVALS IN HOUSEHOLDS WITH 2 CASES OF POLIOMYELITIS, CLASSIFIED ACCORDING TO TYPE OF CASE

Serial interval (days)	No of households				
	2 paralytic cases	2 non paralytic case	Non paralytic, then paralytic case	Paralytic, then non-paralytic case	Total

Unknown	1	0	0	1	2
Total	72	72	31	57	232

Age and Sex Distribution

In table II the age and sex distribution of multiple cases is given, classified as to whether they were primary or secondary. The primary cases include double and triple primaries. It will be seen that there is a curious deficiency of girls aged 6–10 years, which is especially noticeable among the primary cases and for which there is no obvious explanation. This is counterbalanced to some extent by an excess of female adults among the secondary cases. It is reasonable to explain the latter finding as due to infection of mothers by their children. Secondary cases are commoner in females than in males.

Serial Intervals

The distribution of serial intervals among various types of household with 2 cases is given in table III. In character it is very similar in households with 2 paralytic and those with 2 non-paralytic cases, but there seem to be differences between these and the mixed ones. In houses with 2 paralytic cases the 2nd case usually followed the 1st in a short time—about two thirds of them within a week.

Twins

Investigations of twin cases made by Herndon and Jennings (1951) and of consanguinity in parents of paralytic cases by Wintrop Oostenrijk (1955), have suggested the existence of a genetic factor influencing susceptibility to paralysis. Addair and Snyder (1942) have even claimed that susceptibility may be determined by a recessive gene. On the other hand, the work of Borgstrom (1939) and Masini (1953) does not support this possibility. We examined our data for the frequency of twin cases to see whether they were present in sufficient numbers to support the hypothesis of a genetic factor. A rough calculation based on the Registrar General's statistics of household size indicated that about 2·5% of twins might be expected by random sampling alone. It was found that, in 145 households with 2 cases aged less than 16, there were 10 in which the 2 patients had the same name and date of birth. Of 39 paralytic pairs 5 (13%) were twins, while the incidence in mixed and non-paralytic pairs was 1 in 53 (2%) and 4 in 53 (8%) respectively. The excess of twins in the paralytic pairs though suggestive, is not statistically significant.

TERMS OF EMPLOYMENT OF DOCTORS

The present arrangements are full of anomalies The *doctors in government service should* be divided into

(*a*) Professional Civil Servants, including the chief government medical officer (whose salary should be £2000 a year, i e, the equal of the highest ranking Civil Servant), medical officers of health, and port medical officers

(*b*) Clinicians having no relationship to the Civil Service

The appointments of the clinicians should be whole-time (without private practice), or part time and paid on a sessional basis

Those holding conjoint posts (with government and university) would be reckoned as part time clinicians Specialist posts should carry superannuation rights The payment recommended for each weekly session is £175 per annum for the senior consultants and £120–170, according to seniority, for the other consultants A medical superintendent engaged mainly in administration should be paid £1250 and given free board and lodging The junior posts would carry proportionately smaller salaries

There should be scholarships for study abroad free from any legal restriction about future service

THE PRIME MINISTER TO THE NEGOTIATING COMMITTEE

On Feb 26 the Prime Minister published his reply to a letter sent to him by Sir Russell Brain and Dr A Talbot Rogers, joint chairmen of the Negotiating Committee, in which they expressed the committee's dissatisfaction at the Government's decision to appoint a Royal Commission to consider the profession's remuneration claim In the committee's view

" The Government has refused to honour its obligation to apply the terms of the Spens Committee's reports, as interpreted by the Danckwerts award It has thus broken its agreement with the doctors when they entered the health service It has been made clear that the Government does not recognise this obligation, but the late Minister of Health, Mr Turton, said that it would not be right for him to be judge in his own cause "

The committee agreed, however, that the method of adjusting medical remuneration to changing circumstances might usefully be considered They added

" If that stood by itself we should welcome the opportunity of assisting the Government in every way possible But a Royal Commission is no answer to the present claim, and it is manifestly unfair that doctors who have had no compensation for the rise in the cost-of-living for six years should await the result of the slow deliberations of a Royal Commission, and meanwhile be expected to go on loyally and ungrudgingly maintaining the health service though their real incomes remain grievously depressed We therefore ask that the present dispute between us should be submitted to an independent arbitrator without delay "

The text of the Prime Minister's reply is as follows

" Dear Sir Russell Brain I have to acknowledge the letter of February 21 signed by yourself and Dr Talbot Rogers regarding the difficult situation that has arisen in connexion with the remuneration of doctors in the health service

" Naturally I am very sorry that it has not been possible to arrive at an agreed solution of this problem The Government feels that the Royal Commission is the only way in which a permanent system can be devised which will stand the test of time I want to assure you that the purpose of the Royal Commission is not to waste time On the contrary, I shall certainly urge its chairman to proceed without delay Moreover, the work of the Royal Commission would not preclude some interim adjustment

" I must also repeat the Government's offer to deal with *certain classes*, that is hospital officers up to senior registrars immediately

" While I realize the disappointment of your members at any delay I am convinced that in the long run this procedure is likely to improve the relations of the medical profession with the State and the public whom they serve so loyally "

Twins

Investigations of twin cases made by Herndon and Jennings (1951), and of consanguinity in parents of paralytic cases by Wintrop-Oostenrijk (1955), have suggested the existence of a genetic factor influencing susceptibility to paralysis Addair and Snyder (1942) have even claimed that susceptibility may be determined by a recessive gene On the other hand, the work of Borgstrom (1939) and Masini (1953) does not support this possibility We examined our data for the frequency of twin cases to see whether they were present in sufficient numbers to support the hypothesis of a genetic factor A rough calculation based on the Registrar-General's statistics of household size indicated that about 2–5% of twins might be expected by random sampling alone It was found that, in 145 households with 2 cases aged less than 16, there were 10 in which the 2 patients had the same name and date of birth Of 39 paralytic pairs 5 (13%) were twins, while the incidence in mixed and non-paralytic pairs was 1 in 53 (2%) and 4 in 53 (8%) respectively The excess of twins in the paralytic pairs, though suggestive, is not statistically significant

Other Characteristics

The general characteristics of multiple cases, apart from certain features of the age and sex distribution mentioned above, were similar to those of single cases There was no peculiarity of their seasonal distribution, nor were there any obvious changes in the frequency of multiple cases during the four years over which the present data were collected A recent history of inoculation or tonsillectomy was no commoner than in single cases Multiple cases were slightly commoner in rural areas, 30% being found instead of the 22% expected from the Registrar-General's statistics

DISCUSSION

The present study provides little evidence that paralytic cases tend to be associated with one another in households In the whole of England and Wales during four years, there were only 82 households in which 2 or more paralytic cases of poliomyelitis were reported In table IV the observed distribution of multiple cases is compared with that which would have been expected if there had been no association between the cases at all and they were random events in a uniform population of households In these circumstances they would follow a Poisson distribution, and it can be seen that the observed and calculated distributions agree remarkably well There is a significant discrepancy as measured by the χ^2 test, but this could easily be ascribed to the roughness of the hypothesis, which ignores variation in household size and other complications, in any case the χ^2 test is not reliable with distributions of this kind where the major discrepancies are found between very small expectations and their observed counterparts

TABLE IV—COMPARISON OF OBSERVED DISTRIBUTION OF MULTIPLE PARALYTIC CASES IN HOUSEHOLDS WITH THEIR EXPECTED VALUES FROM THE POISSON DISTRIBUTION HOUSEHOLDS WITH NON PARALYTIC CASES EXCLUDED

No of cases in household	No of households	
	Observed	Calculated
0		
1	7603	7600·6
2	72	77·0
3	3	0·4

The distribution of serial intervals is also difficult to reconcile with the existence of a strong association between paralytic cases The distributions in table III relating to pairs of paralytic cases or pairs of non-paralytics are very similar to those that would have been obtained if the members of the pairs had been infected simultaneously by some common source There is no evidence of the existence of a group of cases arising from the primary at about the time of the usual incubation *period* *This finding has also been reported by* Littell and Smith (1955) on the basis of other data on the serial interval, and they have suggested that it could be explained if patients became infectious early enough in the incubation period The work of Casey (1942) does not support this explanation, since it indicates that the infectious period is most commonly from three days before till three days after the onset of symptoms

From a practical aspect the information given above suggests that, so far as a patient's home contacts are concerned, there is little value in quarantine measures or passive immunisation with γ globulin These could not prevent more than about 1% of all paralytic cases even if they were universally applied and completely effective, and every secondary case arose by infection from the primary Furthermore, most secondary cases arise so soon that it would be difficult to take any action in time

SUMMARY

Multiple cases of poliomyelitis, in households in England and Wales from 1951 to 1954, have been studied

In 82 out of 7782 houses in which there was a case of paralytic poliomyelitis, there were 1 *or more* secondary cases This distribution is similar to what would have been expected by chance alone

About two-thirds of the secondary cases arose within a week of the primary

Apparently there was no strong association between paralytic cases

We are indebted to the Medical Research Council committee on inoculation procedures and neurological lesions for permission to use their records We should like to thank Miss Eileen Bebb for her great assistance in the analysis, Dr J Knowelden for his help, and Dr P Armitage for advice and criticism

Poliomyelitis Vaccination

It was hoped that the distribution of poliomyelitis vaccine would start again this week and a batch sufficient to vaccinate 200,000 children with two injections was being made ready But the Ministry of Health announces that information has been received from the manufacturers that signs of possible deterioration during storage have been detected in a few of the phials of vaccine that were ready for issue It has been decided to defer distribution pending investigation During the first phase of the programme last year some 200,000 children between the ages of 2 and 9 were vaccinated, leaving about 1,500,000 children in England and Wales still registered These children are now to be given priority In Scotland about 35,000 children were vaccinated last year, leaving 265,000 children still registered

Medicine and the Law

Negligence Claim Fails

A SCOTTISH jury has unanimously rejected a claim against a doctor for alleged negligence in the injection of an anæsthetic[1] The pursuer (plaintiff) was a Mrs Sutherland She alleged that, in giving her an injection of thiopentone ('Pentothal') before an operation, the doctor negligently caused the point of the needle to enter the median nerve of the left arm It was alleged that as a consequence the patient suffered considerable pain in her left arm and hand from time to time, and that she had difficulty in raising her left arm to the height of her shoulder She also contended that she had defective sensation in the tips of her left thumb and fingers and general clumsiness in her left hand

The defence did not admit that the needle had in fact entered the median nerve, and it does not appear to have been proved that this happened It was admitted, in view of the injury sustained by the patient, that some penetration of the nerve may have taken place, but it was contended that this was not due to any negligence on the part of the doctor Two anæsthetists gave evidence to the effect that any piercing of the nerve could have been due to a completely involuntary muscular movement within the arm which the doctor could not have foreseen or have seen happening

Coma Mistaken for Death

A Mrs L, aged 78, decided apparently to end her life by taking an overdose of drugs[2] Her daughter found her in bed, and believed her to be dead She sent for a doctor who was also of opinion that Mrs L was dead The body was removed to a mortuary, no sign of life being observed during the journey to the mortuary As the undertaker and a police officer were leaving the mortuary, however, the officer noticed that some cotton-wool which had been placed on the woman's face had slipped The undertaker returned and saw that she was breathing Resuscitation apparatus was called for and applied while she was taken to hospital She died later at the hospital

Giving evidence at the inquest, Prof J M Webster said that death was caused by hypostatic pneumonia due to acute narcotic poisoning Mrs L had taken about three times the lethal dose In thirty years' experience, it was only the third case he had known where coma had been mistaken for death and the patient removed to a mortuary

Professor Webster said that the case was a particularly difficult one, because it was in an old lady and the narcotic drugs depressed the vital nerve centres, particularly the respiratory senses In the coma Mrs L had been almost dead, with no pulse at all, and it was a perfectly reasonable mistake to say she was dead The case was almost hopeless from the start owing to the amount of drug absorbed

---

Parliament

Royal Commission on Remuneration

ON Feb 20, in the House of Commons, Mr HAROLD MACMILLAN, the Prime Minister, announced the appointment of a Royal Commission to review the remuneration of doctors and dentists He said

> The House will know that a claim has been submitted for an increase of 24% in the remuneration of all doctors in the National Health Service The extra cost to the country would be about £20 million a year. In present circumstances, the Government do not feel able to admit this claim, and representatives of the profession have been so informed
>
> This does not mean that the Government have reached any conclusion as to the merits of the claim Indeed, they have decided that the time is opportune for a full review of medical remuneration through an independent inquiry which would take into account the position of the medical profession in relation to other professional classes in the community, and would suggest how the matter could be kept under review
>
> Within the last few days a claim, similar to that of the doctors, has been received on behalf of the dental profession, and the dental profession will be included in the review to be conducted by the Royal Commission The question whether the remuneration of doctors and dentists employed by local authorities should be included in the terms of reference is under consideration
>
> I will announce at a later date the names of the chairman and members of the Royal Commission, together with the terms of reference

Mr HUGH GAITSKELL Would the Prime Minister clarify the position ? How long does he expect it will be before the Royal Commission reports ? Is it to be in the nature of an arbitration tribunal which is to pronounce upon the claim ? If so, are we to understand that the Government bind themselves in advance to accept whatever recommendations are made by the Royal Commission ? Will the terms of reference include specialists as well as general practitioners ? Finally, will it be within the terms of reference of the Commission and within its powers to recommend back-dating the award, if there is an award ? The PRIME MINISTER It will of course, be in the power of the Royal Commission to recommend that any award or any proposal should be made retrospective, but we must await the recommendations of the Royal Commission on that point The terms of reference will include the specialists I believe that the character of the Royal Commission will be best set out in detail when I am able to present both the names of the members and the precise terms of reference, but I think it is generally agreed that it would be a good thing if the relation of this profession with other professions could be established and if a satisfactory system could be laid down by which future reviews could be carried out from time to time I think it would be to everybody's benefit if that resulted from the Royal Commission

Sir IAN FRASER While welcoming this proposal, may I ask whether the remuneration of medical auxiliaries such as physiotherapists, radiographers and others who work so closely with the medical and dental profession, could be included in the Commission s considerations ? The PRIME MINISTER. I should prefer not to answer that today, but to take it into account when the terms of reference are settled

Mr HERBERT MORRISON. Does not the Prime Minister think that this is a very doubtful way of seeking to settle wages, salaries, and remuneration ? Does it not take negotiation, from the taxpayer's point of view, out of the hands of Ministers who are responsible to the House and put it in the hands of an outside body ? Is it not unlikely to lead to coördinated responsible decisions ? Does the Prime Minister recall—I admit that this happened under the Labour Government—that the Spens Committee, dealing with somewhat similar circumstances, landed the country into an expenditure and into repercussions which were very embarrassing ? The PRIME MINISTER This is a very difficult problem, but I feel that the work of the Royal Commission on the Civil Service, which is not quite similar but is somewhat parallel has been an advantage Again, it was a question in which Ministers were finally responsible, as they will be in this matter, but I think that it has been an advantage in the general life of the Civil Service. If some equally good results followed from this Royal Commission, I think it would be generally acceptable

Mr G D NABARRO May I ask the Prime Minister to make it perfectly clear, in framing the terms of reference for the Royal Commission, that a primary purpose should be to endeavour to eliminate all the legal and other uncertainties which have arisen during the past few years from the Spens report and the Danckwerts award made under it, all of which are responsible for the present difficult position with the doctor ? The PRIME MINISTER One of the purposes of the Royal Commission will be to clear up this situation and to lay down a system which, through the years, will be more workable and more acceptable

Dr EDITH SUMMERSKILL· As this is virtually a repudiation of the recommendations of the Spens report, could the Prime Minister say what was the reaction of the professional organisations towards this new suggestion ? The PRIME MINISTER The discussions between the representatives of the profession and the Minister of Health are another matter Today, I have simply preferred to confine myself to stating that I have recommended the appointment of the Commission, that Her Majesty has been pleased to accept the recommendation, and that the terms of reference and the membership will be announced I think that all the detailed questions had better be put to the Minister responsible

The appointment of the Royal Commission was announced in the House of Lords by the MARQUESS OF SALISBURY In receiving the statement for the Opposition VISCOUNT ALEXANDER OF HILLSBOROUGH admitted that the statement's first impressions on him were not very cheerful

---

[2] *Birmingham Post*, Feb 19, 1957

Other Characteristics

The general characteristics of multiple cases, apart from certain features of the age and sex distribution mentioned above, were similar to those of single cases There was no peculiarity of their seasonal distribution, nor were there any obvious changes in the frequency of multiple cases during the four years over which the present data were collected A recent history of inoculation or tonsillectomy was no commoner than in single cases Multiple cases were slightly commoner in rural areas, 30% being found instead of the 22% expected from the Registrar-General's statistics

DISCUSSION

The present study provides little evidence that paralytic cases tend to be associated with one another in households In the whole of England and Wales during four years, there were only 82 households in which 2 or more paralytic cases of poliomyelitis were reported In table IV the observed distribution of multiple cases is compared with that which would have been expected if there had been no association between the cases at all and they were random events in a uniform population of households In these circumstances they would follow a Poisson distribution, and it can be seen that the observed and calculated distributions agree remarkably well There is a significant discrepancy as measured by the χ^2 test, but this could easily be ascribed to the roughness of the hypothesis, which ignores variation in household size and other complications, in any case the χ^2 test is not reliable with distributions of this kind where the major discrepancies are found between very small expectations and their observed counterparts

TABLE IV—COMPARISON OF OBSERVED DISTRIBUTION OF MULTIPLE PARALYTIC CASES IN HOUSEHOLDS WITH THEIR EXPECTED VALUES FROM THE POISSON DISTRIBUTION HOUSEHOLDS WITH NON PARALYTIC CASES EXCLUDED

No of cases in household	No of households	
	Observed	Calculated
0		
1	7603	7600 6
2	72	77 0
3	3	0 4

The distribution of serial intervals is also difficult to reconcile with the existence of a strong association between paralytic cases The distributions in table III relating to pairs of paralytic cases or pairs of non-paralytics are very similar to those that would have been obtained if the members of the pairs had been infected simultaneously by some common source There is no evidence of the existence of a group of cases arising from the primary at about the time of the usual incubation period This finding has also been reported by Littell and Smith (1955) on the basis of other data on the serial interval, and they have suggested that it could be explained if patients became infectious early enough in the incubation period The work of Casey (1942) does not support this explanation, since it indicates that the infectious period is most commonly from three days before till three days after the onset of symptoms

From a practical aspect the information given above suggests that, so far as a patient's home contacts are concerned, there is little value in quarantine measures or passive immunisation with γ-globulin These could not prevent more than about 1% of all paralytic cases even if they were universally applied and completely effective, and every secondary case arose by infection from the primary Furthermore, most secondary cases arise so soon that it would be difficult to take any action in time

SUMMARY

Multiple cases of poliomyelitis, in households in England and Wales from 1951 to 1954, have been studied

In 82 out of 7782 houses in which there was a case of paralytic poliomyelitis, there were 1 or more secondary cases This distribution is similar to what would have been expected by chance alone

About two thirds of the secondary cases arose within a week of the primary

Apparently there was no strong association between paralytic cases

We are indebted to the Medical Research Council committee on inoculation procedures and neurological lesions for permission to use their records We should like to thank Miss Eileen Bebb for her great assistance in the analysis, Dr J Knowelden for his help, and Dr P Armitage for advice and criticism

Poliomyelitis Vaccination

It was hoped that the distribution of poliomyelitis vaccine would start again this week and a batch sufficient to vaccinate 200,000 children with two injections was being made ready But the Ministry of Health announces that information has been received from the manufacturers that signs of possible deterioration during storage have been detected in a few of the phials of vaccine that were ready for issue It has been decided to defer distribution pending investigation During the first phase of the programme last year some 200,000 children between the ages of 2 and 9 were vaccinated, leaving about 1,500,000 children in England and Wales still registered These children are now to be given priority In Scotland about 35,000 children were vaccinated last year, leaving 265,000 children still registered

Medicine and the Law

Negligence Claim Fails

A SCOTTISH jury has unanimously rejected a claim against a doctor for alleged negligence in the injection of an anæsthetic[1] The pursuer (plaintiff) was a Mrs Sutherland She alleged that, in giving her an injection of thiopentone ('Pentothal') before an operation, the doctor negligently caused the point of the needle to enter the median nerve of the left arm It was alleged that as a consequence the patient suffered considerable pain in her left arm and hand from time to time, and that she had difficulty in raising her left arm to the height of her shoulder She also contended that she had defective sensation in the tips of her left thumb and fingers and general clumsiness in her left hand

The defence did not admit that the needle had in fact entered the median nerve, and it does not appear to have been proved that this happened It was admitted in view of the injury sustained by the patient, that some penetration of the nerve may have taken place, but it was contended that this was not due to any negligence on the part of the doctor Two anæsthetists gave evidence to the effect that any piercing of the nerve could have been due to a completely involuntary muscular movement within the arm which the doctor could not have foreseen or have seen happening but the worst damage that could be done to the social services would be to allow their cost to rise to unmanageable proportions

Pension Adjustment

On Feb 25, Mr H A MARQUAND called on the Government in their next Budget to increase retirement and old-age pensions and adjust the scales of National Assistance One of the recognised criteria of the adequacy of pensions and benefits was the number of people dependent on them who were obliged to draw National Assistance At the end of last year, he said, this figure stood at 927,000, which in his view justified an increase Another reason for an increase was the continuous rise in the cost of living Since April, 1955, it had risen by 9% He believed that in future there must be a much closer relation between pensions and the level of wages "Means must be found to protect pensions from erosion by inflation He reminded those who said that an immediate improvement in pensions and benefits would throw too heavy a burden on the Exchequer that State support for privately financed superannuation was about £175 million against £137 million for National Assistance

In all, 2½ million people were now dependent on National Assistance and he was uneasy about their standard of living For instance, he did not see how the present rate of *18s* for a child between eleven and sixteen could be fair when a foster parent received *32s* He thought that we should have an authoritative commission to lay down minimum physical standards and set up a cost-of-living index based on these findings

Miss EDITH PITT, joint parliamentary secretary to the Ministry of Pensions and National Insurance, maintained that, though the cost of living had risen, pensions had a better purchasing power today than at any time for the past seven years National Insurance benefits, including pensions, were not, she continued, payments according to needs or means They were paid as a right in return for contribution, and if we were to increase benefits we must also consider increased contributions The Government had no money except what was raised from taxation or contributions Not only must we consider what we could afford but also the burden we were placing on succeeding generations There were today about 4,600,000 retirement pensioners, by the end of 1980 there would be 7½ million To give a £3 pension now would cost an extra £220 million a year, which was equal to *4s* on the joint contribution In twenty-five years it would amount to £370 million or *7s* on the contribution

Turning to the question of nutrition she said that many old people who were found to be lacking food were not short of money but had no friends or relatives to help them According to the National Food Survey for April to June, 1956, the old-age pensioner spent *25s 5d* a week on food compared with *28s 4d* per person in all households She did not think that the allowance paid for a foster child could fairly be compared with an allowance for a child living with its family The boarded-out child went to strangers and some payment was made to them for their care She believed that the Government had protected pensions and benefits and would continue to protect them

QUESTION TIME

Cost of the National Health Service

In answer to a question, Mr DENNIS VOSPER, Minister of Health said that the total cost of the National Health Service for Great Britain in 1949–50 was about £450 million, of which £345 million was met by the Exchequer The corresponding figures estimated for 1957–58 were about £690 million and £550 million respectively The equivalent of these latter figures in terms of the purchasing value of the £ in 1949–50 (measured by the estimated change in the Consumer Price Index between 1949-50 and December, 1956) were about £515 million and £410 million

Mental Diseases and Alcoholism

During 1955 there were 1053 admissions to mental hospitals in England and Wales which were recorded as principally due to alcoholic psychosis or alcoholism No estimate can be made of the number of admissions to mental hospitals in which alcohol was a contributory cause

In England Now

A Running Commentary by Peripatetic Correspondents

AMONG the blights of a casualty officer's life, the common tramp looms large Joshua Smallpiece was the exception to prove the rule

He looked about 80, but he might have been 100 for all we knew He had a grey verminous beard which reached down to the waist and he wore dirty old rags for clothing After his first admission, these were hastily burnt and he complained bitterly about this affront Neither boots nor socks, he claimed, had left his feet for two-and-a-half years, and the students who had assisted in their removal saw no reason to doubt his word

In his way, he was a great naturalist His favourite resting-place lay under the bridge by the river, and in time even the records department came to recognise this as his official residence He lived with the birds and the trees and suffered with the elements In the summer he had sunstroke, in the winter frostbite, the spring showers brought crippling arthritis, while November would bring him cyanosed and gasping feebly, as the fog seeped through his lungs One icy Christmas day, he slipped and broke his wrist The nurses did a wonderful job disinfesting his beard, and he was the best Father Christmas the hospital has ever known

Joshua never outstayed his welcome The first sign of recovery would find him sitting in the grounds on the old wooden bench, throwing crumbs to the pigeons We sometimes thought they knew him, for there were always more of them when he was about But as soon as the strength came back to his legs, nothing would hold him, with his stick and his bundle, he was off on the road, and the long shaggy beard would once again become a familiar sight by the river's edge He had a strange superstition concerning his beard, for he would never allow a single hair to be cut "The day you take my beard off, I die," he said He looked as if he meant it and his wishes were respected

One thundery autumn day, he was brought in unconscious, the victim of a stroke For two days he lay in coma, the long grey beard trailing over his paralysed body like a bale of tow The ward was busy and staff was short "Shave the old man in the corner," called the nurse in charge But the ward had four corners, an old man in each It was too late Joshua's features, seen by us for the first time, showed a ghostly pallor, his expression terrible reproach That evening he wept like a child, and by midnight he was dead

* * *

In our outpost of Empire the cinemas of the town are out of bounds, film shows therefore come to us Our cinema, at other times the company dining-hall, is formed by the end-to-end anastomosis of a series of Nissen huts, internally it is reminiscent of the Bakerloo or prophetic of the airliner of the Future We were agreeably surprised to find one day before Christmas that a film so recent as *Rock around the Clock* was to be our fare The shambles reported in towns in England was not for us, the presence of N C O s in force and the extremely durable furniture militated against this, still, there was nothing half-hearted in our rendering of "See you later, alligator"

Next morning the viva examination for operating-theatre technicians was held Sister presided behind a table on which a selection of surgical instruments was laid out for identification A candidate was handed an instrument and his opinion sought, with only the faintest suspicion of a smile he replied "Dura mater elevator"

* * *

"How's your back?" our orthopod asked solicitously as he got into the lift with me And well he might, for, but for his present girth, he would have stood in my place on the stage during our Christmas show

It is not easy for the tyro to wait for the laugh of recognition, or a sympathetic titter, after the long pause when he has sucked his teeth slowly, flexed and extended his knees that inch or so from the stand-at-ease to the stand easy I was clad only in white paint, plenty of black eye-shadow, and short-sleeved long woollen combinations, and it seemed to me an age before our orthopod

Having regard, he continued, to the long, outstanding application of the great profession of medical men and women to the State service, I feel it is extraordinary that, after this length of time, the question of their remuneration should be referred to a Royal Commission Here we are dealing with something which is urgent, outstanding, and necessary to retain the good will of the medical profession in maintaining a great national service to the people To me, it seems like cowardice on the part of the Government for them not to deal with, and decide their policy upon, what is an urgent matter

There was no such reference to a Royal Commission, no such delay, before the Government made the statement in the other place the other day about the increased costs of welfare milk and the weekly contribution of the worker to the health service as there is going to be in regard to the remuneration of the doctors But here it looks as if the medical profession may be "got at" with a view to putting up with a Royal Commission Having regard to his former association with the great medical profession, no doubt the Chancellor of the Duchy of Lancaster will be busy trying to spin the necessary story of glamour to his professional colleagues

The MARQUESS OF SALISBURY This is a very wide and complex question It is no good the noble Viscount and others saying that the medical profession can be *dealt with entirely in isolation, it cannot be done* This is one of the most complicated questions that exist, as I know from my connections with the research bodies in this country, and it is an eminently suitable question to be dealt with by a Royal Commission

VISCOUNT ALEXANDER OF HILLSBOROUGH How long did it take the Government to discover that this was so complicated a question in comparison with others? For months and months this matter has been under discussion with the medical profession, and it has certainly been within the knowledge of the Ministry of Health from the moment that the State scheme was launched Now, at this stage, when the doctors are in a very poor position—at least, some of them are—in relation to the increasing cost of living, that they should be dealt with by means of a Royal Commission seems to me almost unthinkable Will the noble Marquess say whether, while the Royal Commission is sitting, any adjustment is going to be made to ease the position of the doctors? The MARQUESS OF SALISBURY I understand that my right honourable friends the Minister of Health and the Secretary of State for Scotland have told the doctors and dentists that they are willing to agree to the granting of an interim increase to the junior hospital medical and dental staff This is on the basis that they can justifiably be regarded as underpaid at present The offer will be negotiated through the established Whitley machinery It will not be extended beyond this limited class to, for example, the lower-paid general-practitioner doctors or dentists, it is meant to apply to those who are in most need at the present time

LORD AMULREE I must agree that the questions raised by the medical profession have been going on for a long time and I hope that the Royal Commission will now settle them quickly I very much hope that the position of local-authority doctors and dentists will come under the terms of reference of the Royal Commission This is a matter of some urgency, and I trust that this Royal Commission will report in six months and not a longer period The MARQUESS OF SALISBURY My Lords, the period which the Royal Commission will take is a matter for the Commission The Government desire that it shall be as rapid and efficient as possible in its work

LORD CONESFORD May I ask my noble friend whether, in settling the terms of reference of the Royal Commission, he will consider the advisability of making them wide enough to enable the Royal Commission to compare, not only professional earnings as between different professions, but professional earnings with non-professional earnings? The MARQUESS OF SALISBURY I have said that there must be some limitation of the terms of reference, even of a Royal Commission

⁂ This matter is carried further in correspondence reproduced on p 470 —ED L

Paying for the Welfare State

On Feb 19, on the eve of the publication of the Civil Estimates for 1957–58, Mr PETER THORNEYCROFT, Chancellor of the Exchequer, said that its total was £2654 million, an increase of £110 million over this year Large items in the increase were for education (£63 million) and the National Health Service (£49 million) As a whole the social services showed an increase of £146 million over the original Estimates for this year This was largely due to higher prices, salaries, and wages, but in part it was due to there being more children to be educated and to the increasing use being made of the National Health Service The large and continuing increase in our total expenditure, he continued, imposed a burden on the economy which the Government could not ignore

It would not be right to meet our difficulties by making changes in defence policy alone, and there must also be changes of policy on the civil side Changes in local government finance had been announced The Government had also decided to reduce the subsidies for welfare milk and school meals The price of welfare milk would be increased to *4d* a pint—that is, roughly half price This would leave the subsidy at about the amount per pint at which it was first introduced in 1940 With a corresponding increase in the price of National dried milk, the saving in 1957–58 would be £14 million The charge for school meals would be increased by *2d* to *1s*, saving £3½ million Both these changes would take effect from the beginning of April The existing arrangements for hardship exemptions would continue

Turning to the National Health Service, he said that the Government had given anxious consideration to its growing cost When the service was introduced it was expected to cost a total of £175 million a year By 1949–50, this had risen to £450 million In 1950 a ceiling of £400 million was imposed on Exchequer expenditure, below which the cost of improvements and extensions to the service had to be contained In 1957–58, the total cost of the service would be £690 million Towards this, as things stood now, £40 million would come from the contribution made from the National Insurance Fund, which was *10d* a week for the adult man and lesser sums for other contributors, £100 million would come from other receipts (including charges to patients), and the whole of the balance of £550 million—£49 million above the estimate for last year—would be provided by general taxation

The alternatives to this increase in the charge on the Exchequer were to reduce the scope of the service, to charge more to patients, or to increase the contribution It was widely believed that the National Health Service was paid for by weekly contributions He wished to make it clear that this was not so The contribution had never paid for more than a small proportion of the cost of the service, and this proportion had steadily declined each year When the original National Health Service Bills were before Parliament, it was expected that contributions would provide about a fifth of the gross cost of the service Today, they provided only about a seventeenth The Government, therefore, proposed to increase the contribution by *10d* for an adult man, and by smaller sums for adult women and juveniles The employer would pay the same proportionate share as at present The Government's purpose was to establish a separate National Health Service contribution towards the cost of the service Next year, the contributory element would rise from a seventeenth to about a ninth of the gross cost of the service Separate legislation for this purpose would be introduced as soon as possible The change would provide an additional £10 million for the Exchequer in a full year In view of the rise in the cost of the service he did not think it unreasonable to go back to what was a traditional arrangement—for people to contribute a little when they were well in order that they might be looked after when ill

Members suggested that the increases would fall heaviest on families with small children but the SPEAKER reminded them that these matters would be debated on the Estimates Mr THORNEYCROFT added that the Government had given careful thought to these points, but the worst damage that could be done to the social services would be to allow their cost to rise to unmanageable proportions

Pension Adjustment

On Feb 25, Mr H A MARQUAND called on the Government in their next Budget to increase retirement and old-age pensions and adjust the scales of National Assistance One of the recognised criteria of the adequacy of pensions and benefits was the number of people dependent on them who were obliged to draw National Assistance At the end of last year, he said, this figure stood at 927,000, which in his view justified an increase Another reason for an increase was the continuous rise in the cost of living Since April, 1955, it had risen by 9% He believed that in future there must be a much closer relation between pensions and the level of wages Means must be found to protect pensions from erosion by inflation He reminded those who said that an immediate improvement in pensions and benefits would throw too heavy a burden on the Exchequer that State support for privately financed superannuation was about £175 million against £137 million for National Assistance

In all, 2½ million people were now dependent on National Assistance and he was uneasy about their standard of living For instance, he did not see how the present rate of 18*s* for a child between eleven and sixteen could be fair when a foster parent received 32*s* He thought that we should have an authoritative commission to lay down minimum physical standards and set up a cost-of-living index based on these findings

Miss EDITH PITT, joint parliamentary secretary to the Ministry of Pensions and National Insurance, maintained that, though the cost of living had risen, pensions had a better purchasing power today than at any time for the past seven years National Insurance benefits, including pensions, were not, she continued, payments according to needs or means They were paid as a right in return for contribution, and if we were to increase benefits we must also consider increased contributions The Government had no money except what was raised from taxation or contributions Not only must we consider what we could afford but also the burden we were placing on succeeding generations There were today about 4 600,000 retirement pensioners, by the end of 1980 there would be 7½ million To give a £3 pension now would cost an extra £220 million a year, which was equal to 4*s* on the joint contribution In twenty-five years it would amount to £370 million or 7*s* on the contribution

Turning to the question of nutrition she said that many old people who were found to be lacking food were not short of money but had no friends or relatives to help them According to the National Food Survey for April to June, 1956, the old-age pensioner spent 25*s* 5*d* a week on food compared with 28*s* 4*d* per person in all households She did not think that the allowance paid for a foster child could fairly be compared with an allowance for a child living with its family The boarded-out child went to strangers and some payment was made to them for their care She believed that the Government had protected pensions and benefits and would continue to protect them

QUESTION TIME

Cost of the National Health Service

In answer to a question, Mr DENNIS VOSPER Minister of Health said that the total cost of the National Health Service for Great Britain in 1949–50 was about £450 million, of which £345 million was met by the Exchequer The corresponding figures estimated for 1957–58 were about £690 million and £550 million respectively The equivalent of these latter figures in terms of the purchasing value of the £ in 1949–50 (measured by the estimated change in the Consumer Price Index between 1949–50 and December, 1956) were about £515 million and £410 million

Mental Diseases and Alcoholism

During 1955 there were 1053 admissions to mental hospitals in England and Wales which were recorded as principally due to alcoholic psychosis or alcoholism No estimate can be made of the number of admissions to mental hospitals in which alcohol was a contributory cause

In England Now

A Running Commentary by Peripatetic Correspondents

AMONG the blights of a casualty officer's life, the common tramp looms large Joshua Smallpiece was the exception to prove the rule

He looked about 80, but he might have been 100 for all we knew. He had a grey verminous beard which reached down to the waist and he wore dirty old rags for clothing After his first admission, these were hastily burnt and he complained bitterly about this affront Neither boots nor socks, he claimed, had left his feet for two-and-a-half years, and the students who had assisted in their removal saw no reason to doubt his word

In his way, he was a great naturalist His favourite resting-place lay under the bridge by the river, and in time even the records department came to recognise this as his official residence He lived with the birds and the trees and suffered with the elements In the summer he had sunstroke, in the winter frostbite, the spring showers brought crippling arthritis, while November would bring him cyanosed and gasping feebly, as the fog seeped through his lungs One icy Christmas day, he slipped and broke his wrist The nurses did a wonderful job disinfesting his beard, and he was the best Father Christmas the hospital has ever known

One thundery autumn day, he was brought in unconscious, the victim of a stroke For two days he lay in coma, the long grey beard trailing over his paralysed body like a bale of tow The ward was busy and staff was short "Shave the old man in the corner," called the nurse in charge But the ward had four corners, an old man in each It was too late Joshua's features seen by us for the first time, showed a ghostly pallor, his expression terrible reproach That evening he wept like a child, and by midnight he was dead

* * *

In our outpost of Empire the cinemas of the town are out of bounds, film shows therefore come to us Our cinema, at other times the company dining-hall is formed by the end-to-end anastomosis of a series of Nissen huts internally it is reminiscent of the Bakerloo or prophetic of the airliner of the Future We were agreeably surprised to find one day before Christmas that a film so recent as *Rock around the Clock* was to be our fare The shambles reported in towns in England was not for us, the presence of N C O s in force and the extremely durable furniture militated against this still, there was nothing half-hearted in our rendering of "See you later, alligator"

Next morning the viva examination for operating-theatre technicians was held Sister presided behind a table on which a selection of surgical instruments was laid out for identification A candidate was handed an instrument and his opinion sought with only the faintest suspicion of a smile he replied "Dura mater elevator"

* * *

"How's your back?" our orthopod asked solicitously as he got into the lift with me And well he might, for, but for his present girth, he would have stood in my place on the stage during our Christmas show

It is not easy for the tyro to wait for the laugh of recognition, or a sympathetic titter, after the long pause when he has sucked his teeth slowly, flexed and extended his knees that inch or so from the stand-at-ease to the stand easy I was clad only in white paint, plenty of black eye-shadow, and short-sleeved long woollen combinations, and it seemed to me an age before our orthopod introduced me in stentorian tones as LITTLE MR BIG Then simulating utter weariness I presented the arms-bend position and gazed slowly in turn at each of the small biceps bumps formed (I may mention here that I am very thin)

I had been told to slow up my movements even more if I found the audience "dead," which I did Also as a face-saver to turn my back ("Show your gorgeous trapezii, old boy") on the audience and still with arms bent do a slight gyration with the hips Many years ago this had gained a coarse guffaw from the rear of the hall when the orthopod had saved the same turn from going sour He assured me it would start a laugh riot and panic the audience Unfortunately, without benefit of rehearsals or stagecraft, it was I who panicked, and without waiting any longer I started, with a quick nod to the pianist a too quick rendering of *You too can have a body like mine* At the third line I had lost the artificial quavering croak which had taken a lot of bathroom practice and I searched my vocal chords to resuscitate it without success Leaving the pianist behind, I now gained speed and forgot to gaze in meditation at my navel for the long pause after *make your liver shiver and your kidneys quiver*

In the corner of my eye I noted restlessness in the wings as well as in the audience, and I started on the deep-breathing exercise ("It has to be done very, very slowly, old boy, it's the punch moment of the whole item"), which our orthopod said would tie everybody in knots providing I gained the audience's confidence Neither I nor the audience had any confidence, and the deep breathing degenerated into short pants Once more I hurried into the refrain and began to sense escape was near

I shuffled to the cunningly dispensary-painted "plaster-of paris" bar-bell weights which had been placed front centre-stage only to find that the orthopædic department had left a genuine 60 lb on each end of the bar As I swore and tore to raise it for the "snatch, clean and jerk" I felt the ominous click and the sharp pain in my back Bent double I made my exit holding up one end 18 in from the floor

The gratifying roar that resounded on my disappearance was due, I was told later, to the beaming genial aplomb of our orthopod, who, exhaling good cheer and sparing me the insult of the desultory clap, swung with a crash of opening bars straight into *I'm the man who found The Lost Chord*

* * *

The B B C News Service had just told of last month's earth tremors A professor of geology from the Midlands was reported to have said that the shock wave was so severe that it "nearly threw him from his chair" A colleague commented that if this was the usual effect of earthquakes then our little university town might well benefit by a series of seismic shocks

* * *

The dominant gene, the dominant gene
Is the happiest creature that ever was seen,
We mortals can only admire at a distance
The joys of a chromosomatic existence—
Or marvel how Nature determines the sexes
By cunningly mixing the Y's and the X's
(For as Mendel has proved, it is only statistics
That settle our primary characteristics)
Just imagine the life of ineffable bliss you
Could spend as a speck in the nuclear tissue!
Fraternally twinned with a charming recessive—
Your relationship tender, but firmly possessive,
Dictating the pigment, the shape of the nose,
Or whether your host shall have suckers for toes
Do you find immortality's promise seductive?
Make your home in a cell that is marked "Reproductive"
A short life, but merry? You dread being static?
Your calling is plain—you are clearly Somatic—
For you cannot grow stale, with your every ambition
Fulfilled by perpetual cellular fission
So banish your doubts, your neuroses, and revel
In life as it's lived at molecular level!

By shuffling two chromosomes—split down the middle

Letters to the Editor

BRONCHIAL CARCINOMA

SIR,—Mr Thompson, in his letter last week, draws attention once more to the delay in referring patients with cancer of the lung to the surgeon One reason for this delay will be appreciated by all whose task it is to recognise cancer of the lung among other diseases with identical presenting symptoms and radiological findings They see many patients with persistent cough due to a respiratory infection, pulmonary consolidation resolving slowly but permanently under treatment, and blood in the sputum the source of which is an acutely inflamed bronchial mucosa Any one of them may be suspected for a time of having cancer If they were all sent to a thoracic surgical department without preliminary sorting the surgeons would soon find themselves overwhelmed Mr Thompson's figures, illustrating the slow progress of his patients from the general practitioner to the surgeon, cannot therefore be seen in perspective unless we know the size of the sick population from which they were drawn For every one of his 135 patients with carcinoma of the lung there must have been many others who did not go beyond the general practitioner or the chest physician, because they were found to have some less serious disease during the seemingly long period of observation

Just over a year ago a group of six general practitioners agreed to refer to me every man aged 45–70 years who had been a heavy smoker as soon as he reported one of a previously defined set of symptoms suggesting the possibility of bronchial carcinoma The number of patients referred to me under this arrangement in 1956 was 56 Amongst these I found 2 with bronchial carcinoma, only 1 of whom was in a fit state to be referred to the surgeon It was often impossible to settle the diagnosis at the first consultation, and many patients were seen several times before being dismissed from observation If Mr Thompson's suggestion had been adopted, he and his colleagues would have examined over 7500 patients, many of them more than once, in order to find 135 cases of cancer of the lung This conservative estimate is based on the assumption that his patients were also selected from a similar age group of men at special risk

The special techniques available to thoracic surgeons, by which Mr Thompson probably means facilities for bronchoscopy and thoracotomy, are readily accessible everywhere The difficulty is to know when to use them Most patients find bronchoscopy too unsettling an experience for it to be used on the large scale necessary for efficient case finding Nobody would wish to rely on thoracotomy as a means of diagnosis except as a last resort There is no such objection to a search for malignant cells in the sputum, but this examination demands great skill and is time consuming It remains to be seen whether it is economical to provide such a service on the scale required for general use

It would be unprofitable to discuss whether this or that class of doctor is better qualified to recognise cancer of the lung in its early stages If the arrangements we are testing on a small scale were extended to the whole population, the work involved would overstrain the resources of any one specialty

Queen Mary's Hospital
Sidcup

PAUL FORGACS

SIR,—It is extraordinary to find such a distinguished surgeon as Mr Vernon Thompson blaming the medical profession for the failure to diagnose lung cancer earlier and making the misleading suggestion that the present tendency "to refer chest cases to chest clinics, which have evolved from the old tuberculosis dispensary, in order to get an X ray, has contributed largely to the delay."

It is surely common knowledge that when patients complain of respiratory symptoms, elucidation of their condition requires a chest X ray. Indeed, as Mr Thompson himself says, "radiology is now an essential part of clinical examination," and today the overwhelming majority of general practitioners know this and refer their patients liberally to the most convenient centre. All over the country efficient chest clinics are now in existence doing this work, and, owing to the recognition of the importance of radiology, enormous strides have been made toward the earlier and effective diagnosis of all pulmonary conditions.

Mr Thompson cannot be serious when he suggests that "general practitioners who suspect that their patients have carcinoma of the lung should be encouraged to send them direct to surgical centres. There are enough fully trained thoracic surgeons to deal with the problem." Does Mr Thompson really suggest that general practitioners should send all their patients with cough or sputum or hæmoptysis or dyspnœa or chest pain to such thoracic surgical centres for investigation? There are less than one hundred consultant thoracic surgeons in England and Wales. It is quite certain that every consultant thoracic surgeon would be so swamped with such diagnostic work that he would at once cease to have any time to operate. At this clinic, a general practitioner can obtain an X-ray report on any patient within twenty-four hours without making a special appointment. In 1955, over 2000 patients were referred to this clinic complaining of respiratory symptoms. A large proportion of these had symptoms which are common to lung cancer and to other lung diseases.

Unfortunately Mr. Thompson bases his illogical argument on 135 selected cases of lung cancer which had found their way to a single teaching hospital in 1954. It is well known that patients who find their way to teaching hospitals commonly do so because they are not straightforward cases, and the conclusions to be drawn from such a series must be interpreted with that in mind. It is astonishing that Mr Thompson quoted 3·8 months as the average interval between a patient seeing a chest physician and coming to his department. We find it difficult to believe that such a state of affairs in any way represents common clinical practice in England today. If any one of us had a patient who could not be bronchoscoped at any thoracic centre within a fortnight on our recommendation, that patient would straight away be referred elsewhere for bronchoscopy, but in practice we enjoy the closest cooperation with the thoracic surgeons with whom we are associated.

The earlier diagnosis of lung cancer, as of pulmonary tuberculosis, is to be achieved by the wholehearted coöperation of every branch of the medical profession together with highly efficient hospital organisation in regard to outpatient appointments and inpatient investigation.

W H TATTERSALL
D J APSIMON
A T HENDRY

SIR,—Mr Thompson's strictures about procrastination by chest physicians when diagnosing carcinoma of the bronchus have led us to examine from this angle all our cases diagnosed in 1956.

We serve a population of about 300,000 from which general practitioners have free access to our X-ray-only service. 8605 patients were sent up of whom we recalled 381 for clinical examination and 43 were finally diagnosed as carcinoma of the bronchus (this includes cases referred direct for appointment). In these 43 cases the average time from initial X ray until bronchoscopy was 2½ weeks and the further interval until thoracotomy was 2½ weeks. Much of the credit for these figures is due to our surgical colleagues for their close coöperation.

There can be little room for criticism of delay in these figures, and in fact about half the delay before operation is the time awaiting a surgical bed once bronchoscopy has confirmed the diagnosis. It would be interesting if Mr Thompson's figures could be completed by giving the average interval from diagnosis until thoracotomy, as in our experience this even if unavoidable, is not always negligible.

While we feel justified in doubting whether any other method would reduce delay still further, we must admit that 2 of our cases had previous films at the clinic about a year and two years before, and on looking back we had obviously missed the small original lesion. We are aiming to avoid this in future by independent double reading of all new films, but do not feel it affects the present argument.

We would, however, be very willing to have instruction from the character who apparently in Mr Thompson's estimation could have picked out on one small postero-anterior film the 20 cases which should be referred for surgery out of the 381 recalled for examination. It took us much time with further radiological, clinical, and pathological examination, not to mention about 80 bronchoscopies, to weed out these 20 apparently operable cases. Any shortening of the process would be welcome.

We understand that each thoracic surgeon serves about half a million of the population, and it is quite unrealistic to suggest he could tackle this preliminary sifting of cases as well as perform the surgery.

Thoracic surgeons are peculiarly fortunate among their surgical brethren in having most of their cases presented to them already worked out by physicians. This leads to a rather Olympian outlook, and we would warn them that a descent to primary contact with the patient might lead to humiliation; they too might be subject to observer error.

Isolation Hospital,
Norwich

P H SUTTON
A H C COUCH

SIR,—Every thoracic surgeon in this country will sympathise with Mr Frank Nicholson (Feb. 9) and Mr Vernon Thompson in their anxiety to improve the diagnosis of this dread and relentlessly increasing disease.

There still seems to be a proportion of family doctors who regard bronchial carcinoma as a sufficiently uncommon disease not to consider it in patients presenting with an acute respiratory illness for the first time in their lives, or in those complaining of a cough or wheeze, hæmoptysis, "tightness of the chest," or even frank dyspnœa. I have purposely excluded pain from my list of important symptoms, for I have come to regard it as a late and sinister feature indicating inoperability in many cases.

It is interesting to notice how many patients are becoming aware of facilities available to them, and after a period of treatment from their own physician have themselves requested a radiograph only for an inoperable growth to be discovered.

Admittedly there is a risk that a tuberculosis-minded physician may lose time watching the effect of antituberculous drugs on a radiological shadow, perhaps caught off his guard by the finding of tubercle bacilli in the sputum, whereas a simple inspection through the bronchoscope would have revealed an unsuspected concomitent tumour. I would hesitate, however, to throw the weight of diagnostic responsibility on to the radiologist on whose report the family physician may have to depend. Very few radiologists have the time or the facilities to conduct a careful appraisal of the patient's history and symptoms, and still less to examine him clinically—steps which may be of critical importance, and are, therefore, tempted to fall back on the formula of a "follow up examination in 4–6 weeks"—a process which, if two or three radiologists are each reading films in a busy department, may add several months to the diagnostic time

What is the answer? Some years ago Sir Russell Brock advised that any patient over the age of 40 suffering from an attack of pneumonia ought to have a chest X-ray before returning to work I venture to suggest that over the age of 30 would be even better Furthermore, one notices nowadays that the astute physician seeing a patient who is presenting with symptoms referable to the chest for the first time, or with a change in his respiratory history, now arranges for a radiograph, and if an abnormal shadow is visible on the films he then refers his patient to a thoracic surgeon for an opinion This course of action does, I believe, conform with Mr Thompson's criteria of making the full range of diagnostic facilities, by bronchoscopy, bronchography, and if necessary thoracotomy, immediately available to the patient and may save a great deal of valuable time in treating a disease which manifests itself with unpleasant frequency at a distressingly late stage

Blackpool
P JEWSBURY

UNMARRIED PARENTHOOD

SIR,—Dr Comfort's letter (Jan 26) was most welcome The problem of unmarried motherhood is, however, part of a larger problem—that of the unwanted child The desirable situation is that every child should be positively desired Ignorance of contraception not only causes undesired extramarital pregnancies, it also causes many unwanted children to be born in wedlock And while it is probably true that most mothers come to accept these pregnancies in the end (only a minority of the babies so conceived come to be classed as rejected children), yet there is a world of difference between such acceptance and the joyful welcome of a child whose conception was positively desired

Furthermore security in the matter of contraception extends a beneficial effect far beyond the question of desired or undesired pregnancies, for it provides the basis for a sexual life freed from such anxieties Family doctors of discernment have known many cases where family life has been disrupted by pregnancy anxiety with its attendant destruction of sexual fulfilment, and a high proportion of the illnesses which stem from anxiety can be traced to this same pregnancy anxiety Coitus interruptus has long been known to exert a baleful effect upon those who practise it, yet the prevalence of this crude method is itself an indication of the ignorance regarding more rational and æsthetic techniques

The field of medicine in which knowledge of reliable contraceptive techniques can be of profound help is therefore enormous The family physician is the obvious person to disseminate information and create a healthy attitude, but he is severely handicapped by the fact that the teaching hospitals do not regard it as their responsibility to give any guidance to students about contraception (as far as I know, University College Hospital is the only London teaching hospital to have a contraception clinic) Even today it is not unusual for women to be advised by gynæcological clinics against further child bearing without any advice being added as to how pregnancy is to be avoided This has happened several times in my practice despite the existence of an excellent birth control clinic in the district The training of doctors in contraceptive techniques is undertaken by the Family Planning Association, but it is left entirely to individual doctors to discover the usefulness of such knowledge, and to decide to acquire it Here is a field in preventive medicine which is largely unrealised, but which can yield rich results in helping to prevent unhappy homes, and the bringing into the world of unwanted or only half-wanted children It is to be hoped that those in charge of medical education will soon realise their responsibilities in this matter

London, S E 1
JOHN HEWETSON

BIRTHDAYS OF SPASTICS

SIR,—Dr R T Bevan's letter of Feb 16 prompted me to review the birth dates of 227 known spastics born in the years 1940 to 1953 in the County of Stafford

The monthly incidence from January to December was 17, 20, 21, 18, 27, 26, 21, 12, 15, 15, 17, 18 These figures do not show the distribution recorded by Dr Bevan, for in the period December to March 76 cases had their birthdays whilst the period June to August accounted for 59 cases The lowest incidence in this series was in the months July to September—42 cases

Wolverhampton
C SIMPSON SMITH

PRACTITIONER AND LOCAL AUTHORITY

SIR,—I was somewhat puzzled by a phrase in your leading article of Feb 2 "And, if one can judge by the correspondence in our columns, most doctors think " One would accept this level of reasoning in The Widdicombe File but not in your editorial columns

I believe the number contributing to the correspondence was 26 What proportion of 26 supported the original anonymous contributor is evidently a matter of opinion I thought the balance was remarkably evenly held, even without allowing for the relative numbers of general practitioners and of local authority medical officers in the profession

My quarrel with your phraseology is that neither the total of 26 nor any part of it constitutes a significant proportion of the medical profession It could be that "most doctors" did not think an anonymous gibe was worth powder and shot

Ethics have been mentioned What of the ethics of blackguarding, under a nom-de-plume, a section of the profession of which the writer admittedly knew little All in fun? Perhaps, but from the young man's final contribution he evidently expected to be taken seriously If, in the course of his professional career, he never comes across anything more unethical than clinic services he will be fortunate

Galleywood, Essex
HILDA MENZIES

THE Rh BLOOD-GROUPS

SIR,—I am sorry to prolong this correspondence, but Dr Wiener (Feb 16) has so grossly misquoted me as to require an answer

I did not say that the use of "most likely genotypes" leads to paradoxes—far from it My complaint was that he had interpreted one of his tables as if each genotype were a certainty *instead of being one of several possibilities as the words* "most likely" surely imply There is in fact *no* paradox in either table presented in either notation *All that* can be said is that two of the tables are less complete than the other two (a fact clearly *indicated* in their headings) *It* requires neither legal *nor scientific* acumen to realise that they are unsuitable for paternity work where interest lies in impossibilities and not probabilities, however high

I find it difficult to reconcile the beginning and the end of Dr Wiener's second paragraph He says that workers use the CDE system because they understand no other, but that they would find it easy to change because they already use the "shorthand" symbols and, therefore, have nothing fresh to learn Really, Sir, he cannot have it both ways

Dr Wiener's third paragraph proposes an odd use for his nomenclature He seems to be suggesting that it should be used to impress (and presumably baffle) lawyers, who, he thinks, might suspect that a CDE user did not understand his subject The reaction of an English barrister to evidence in Wiener's notation is easy to predict "Thank you, Doctor Now would you mind explaining to My Lord and the Jury in simple English just what you mean?"

J W NICHOLAS

REMUNERATION IN HOSPITAL SERVICE

SIR,—Your correspondence columns have recently included letters in connection with the status and remuneration of pharmacists, laboratory technicians, and radiographers, and Mr David White (Feb 16) indicated that the discontent embraced the whole field of medical auxiliaries

The medical profession itself is seething with discontent regarding its conditions and remuneration Recent letters to the *Times* indicate that there are similar causes for concern over the remuneration of catering officers and chefs Administrative workers are equally dissatisfied with conditions and rewards

It is clear, therefore, that all who are working in the hospital branch of the National Health Service are dissatisfied with the rewards available for ability and effort, and I suggest that there is a great need for representatives of all branches of the professions engaged in the health service to meet with a view to presenting a general demand to the Minister for an early review of the whole question of remuneration to hospital service staffs, particularly with reference to the methods of negotiation

Aylesbury Bucks

RONALD MACDONALD

THE DISINTEGRATIVE ACTION OF THE NERVOUS SYSTEM

SIR,—The Bradshaw lecture of Dr William Phillips, published in your issue of Feb 9, is a fine contribution to that holistic or integrative medicine which dominates contemporary thought and practice We must be grateful to him for having again stressed the importance of the psychological factors in disease and of the consideration of the patient as a person, in a true Hippocratic spirit

There is, however, a certain danger of swinging the pendulum too far, and this was pointed out at the Third International Congress of Neohippocratic Medicine Even psychiatrists are beginning to return patients referred to them to the hospital departments from whence they came The only way to avoid this danger is to insist on an accurate nosological diagnosis We have to start our medical handling by labelling the patient and placing him under one of the morbid categories of nosology The famous slogan of Peter "There are no diseases, but only patients" ought to change into "There are diseases *and* patients" History has shown that neglect of this first step in diagnosis renders all our subsequent individual consideration of the patient often useless The failure of the German "physiological" school of the 19th century, so well described by Sir Francis Walshe in his Gowers lecture,[1] is a recent demonstration of that historical law It is after an accurate nosological diagnosis that personalistic investigation, psychological, physical and environmental has to be considered

I am astonished, however, to note in Dr Phillips's fine lecture that he is amazed that intelligent people consider that a classical education trains the mind in some unique fashion and that "the old ways of thought inherited from the Greeks and Hebrews, and modified at the Renaissance, will gradually change" Is not our integrated holistic medicine of today based on our Greek classic, Hippocrates? Do we not find in Plato the principle that physicians to cure a local disease have to treat the whole body and mind? Do we not encounter in all ancient Greek medical observations the stress on social environmental factors, including worry about the payment of the fees? Can we find a better insight into the human mind than in the Greek tragedians, *The Bible*, and Shakespeare? Dr Phillips accepts the opinion of Putman that a thorough preliminary course in psychology and philosophy, following close on chemistry and physics, is the best preparation for medical practice The philosophy that has not been inherited from the Greeks and Hebrews is that of crossword puzzles that delights dons far removed from active life, and that which leads to inhuman totalitarianism and universal extermination The philosophy necessary for us physicians is that inherited from the Greek thinkers, who were essentially men of action, in daily contact with the rough and tumble of life, and from the great Hebrew prophets, who opened our eyes to the transcendent and spiritual value of life We have, of course, to augment that heritage, but we cannot do away with it if we do not wish our civilisation to be buried in the sands, like all those ancient civilisations that had done away with their spiritual values

A P CAWADIAS

OBSTETRIC FLYING-SQUADS

SIR,—In the light of your annotation last week reporting the 21st anniversary of the Newcastle Obstetric Emergency Service, may I mention what, as far as I am aware, was the first "flying-squad" to be set up in the County of London?

In 1938, Prof F J Browne, on behalf of the University College Obstetric Hospital, agreed to provide a hospital flying squad for mothers in this borough The staff of the unit comprised a physician of consultant standing, with three alternative consultants to act as deputies, one medical officer to act as assistant to the consultant, and one qualified nurse The borough council also agreed to pay the hospital a fee of seven guineas for each occasion upon which the unit was called out A report from the doctor or midwife calling out the unit was asked for as soon as possible, and the cooperation of the police was also obtained to cope with any possible difficulty in calling the unit

The number of calls upon the unit was few at first, but increased as time went on, and there were nine emergency calls in 1946, and ten in 1947 The following two cases, taken from my 1947 annual report, are typical

CASE 1—The flying squad was called at 11 20 P M The patient, aged 22, had been delivered of her first baby and immediately after delivery of the placenta there had been a very severe postpartum hæmorrhage with the loss of 80 oz of blood The patient was found to be in a state of collapse with a pulse rate of 140 and blood pressure of 80/50 Patient was given plasma and blood transfusion one pint of each, and morphine, and with this treatment she made a very satisfactory improvement and the flying squad left the house at 1 A M

CASE 2—The flying squad was called at 10 A M and the unit arrived at the house at 10 20 A M The patient was found to be in a state of obstetric shock suffering from postpartum hæmorrhage Her blood pressure was 80/50 and her pulse rate about 100 An immediate transfusion (group O, Rh negative) was put up and manual removal of the placenta was carried out under chloroform anæsthesia The transfusion was completed and the patient received a total of 420 ml of blood and 300 ml human serum A course of penicillin and sulphathiazole was ordered At 11 30 A M the patient s condition showed a great improvement, there being no further bleeding, the blood pressure was 130/70 and the pulse rate 110 The patient s general condition was satisfactory when the unit left the house at 11 40

The borough council's arrangement for the flying-squad was terminated on July 5, 1948, when responsibility for the personal health services passed to the London County Council as the local health authority under the National Health Service Act, 1946

TOWARDS PREVENTING SUICIDE

SIR,—We should like to thank correspondents who have written concerning our paper "Towards Preventing Suicide" We set out to establish that more common admission to hospital is one effective answer to the increasing total mortality from suicide To achieve this we concluded that changes must be brought about in public attitude and professional awareness It was not our purpose in a short article to discuss either the ætiology or the prevention of suicide in a comprehensive way, and it was not suggested that admission to a mental hospital is the only worth-while preventive measure If our figures are representative of what happens in the country as a whole, it means that of an annual total of about 5000 suicides, 2650 are not under medical care at the critical time, but 2000 are under medical care including 500 who have been seen by a psychiatrist but not admitted to hospital Admission may have been advised and refused, and it may be the right decision in individual cases, after full assessment, not to advise admission to hospital But these figures suggest that admission is not achieved sufficiently often, and either the patient or perhaps the doctor too often contracts out of the best proven method of preventing suicide

IAN SKOTTOWE

Warneford Hospital, Oxford

DEPOT TUBERCULIN

SIR,—Last May Dr James and Dr Pepys described a technique for giving purified protein derivative of tuberculin (P P D) in an emulsion of light liquid paraffin and anhydrous lanolin, as a tuberculin test[1] This "depot tuberculin" remained in the skin for two or three months and became "positive" as the patient's allergy developed, or, if the patient was a positive reactor, it gave a reaction in forty eight hours The method seemed to have an important bearing on B C G work, and indeed Dr James and Dr Pepys had used it in conjunction with B C G in 9 cases If depot tuberculin were given at the same time as B C G vaccination, the result could be read at the same time as the vaccination was inspected, thereby simplifying procedure The authors had seen no non-specific oily reactions, and said that the positive result disappeared within three months

This has not been our experience at Great Ormond Street Between May and November, 1956, we gave depot P.P D to 200 people (142 newborns, 38 older children, and 20 adults) with the following results

Uncontrolled	
P P D in vehicle negative, Mantoux positive (10 units)	40
P P D in vehicle positive Mantoux negative (10 units)	1
P P D in vehicle positive, no Mantoux test	88
Controlled against Vehicle	
P P D in vehicle positive, vehicle negative	23
P P D in vehicle positive vehicle positive	17
(But P P D reactions larger than control reactions)	
P P D in vehicle negative, vehicle negative, Mantoux positive	7
Equal reaction to P P D in vehicle and to vehicle alone	2
Reaction to vehicle greater than reaction to P P D in vehicle	1
All tests negative	2
Failed to return for reading	19

Thus no fewer than 47 cases out of 200 were negative to P P D in the oily vehicle, although positive Mantoux reactions demonstrated that the patients had developed sensitivity to tuberculin For this reason alone we would not regard this test as reliable

Secondly, in several cases there was no difference—or very little difference—between the reaction to P P D and the reaction to the vehicle alone, indeed, in one case the latter was the greater!

Thirdly, after six months some patients still have a dusky red indurated area about half an inch in diameter which shows no signs of disappearing Although painless, this is æsthetically very unpopular and is probably the greatest disadvantage of depot tuberculin

I am drawing attention to our results because others may encounter the same difficulties We do not feel we can recommend this technique at present

Great Ormond Street, London, W C 1

MARCIA HALL

THE FUTURE OF NURSING

SIR,—Dr Thomas Anderson's latest letter (Feb 9) spurs against my laziness in not writing before The majority of student nurses do not possess the intellectual capacity for university training and few receive financial support from their parents after leaving school They are anxious to engage in practical nursing as soon as possible without lengthy preliminary academic training, for such, the present State training is perfectly adequate and they rapidly realise their prime ambition, which is the emotional satisfaction of nursing the sick patient There would be a severe drop in the general entry to nursing if a university-trained cadre was available, the simple S R N would feel hopeless of ever attaining high rank in her calling and no longer would a matron's baton be present in any probationer's knapsack Already an excessive theoretical knowledge is demanded my lectures in surgery to nurses are up to Conjoint diploma level No one can decide a nurse's future quality at the age of 18, and her outlook and possible late mental development may make her a very different person at 21 The advanced course of training should be available after general training has been completed—at the stage of being about to take a ward sister's post when such a course would be of great value

A nurse will always be subordinate to the doctor because he will always dictate the main line of treatment and take the major responsibility If a nurse finds her work intellectually unsatisfying then she should (as many have) embark on medicine At all costs let us avoid the appalling hybrid of nurse cum doctor as envisaged by one of your correspondents of senior nursing rank, though Miss Edwards's wise letter was a reassuring counterbalance

Wolverhampton

ERIC DOLTON

SIR,—One month after my 18th birthday I entered the preliminary training school of a large teaching hospital in Cape Town. Six weeks later I was sent to a surgical ward as its most junior nurse and spent by far the greater part of my time making beds, giving out bedpans, keeping the sluiceroom clean, and washing dirty bed linen We were also required to do a certain amount of purely domestic work, such as dusting and washing up

After two months of this I still felt exhausted every evening (one was almost never off duty dead on time), but as the atmosphere of the ward was cheerful and few of the cases chronic I had no doubts about carrying on I was then sent on night duty as an extra relief—a job which involved moving round from ward to ward wherever additional help was needed, and one which usually went to the most junior nurse on duty During my first three weeks of this I nursed the following cases a two and a half year old girl dying of tuberculous meningitis, a young man in the terminal stages of laryngeal carcinoma whom I specialled for three nights until he died, and a case of advanced pemphigus who smelt so appalling that joss sticks were burnt in the room Every morning I was required to change and sluice his linen and every morning

---

[1] James D G Pepys J Lancet 1956 i 602

I was sick. What made things a great deal worse was that there was virtually nothing I could do to help any of the three.

At the end of the three weeks I went to my family doctor who was the only person with whom I felt I could discuss things and told him what I had been doing and that I felt I could not carry on Other girls might be able to cope but I had had too much. He told me that if I could stick it I should as I would never come across anything worse I took his advice, found that what he had said was true, and finished my training

One does not wish to give too gloomy a picture During those three and a half years I enjoyed myself a great deal both on and off duty, and made many friends. I never regretted for long my decision to stay But during that first on the whole very unhappy year I worked under only one ward sister who tried to help me as an individual and who taught me what nursing could be at all levels.

Now I have a very small daughter and if she should wish to become a nurse I shall try to dissuade her from starting until she is 21—that is unless all the people, matrons, sisters. tutors and particularly doctors. who are concerned with the training of student nurses have made a real and sympathetic attempt to understand the special problems they are called upon to face

Lincoln **CLODAGH WILKINSON.**

"REGISTRARS"

SIR,—Since hospital registrars no longer compile the register could they not revert to the title of assistant—first, chief, senior, junior, medical surgical, or what you will?

St Mary s Hospital
London, W.2

A J HARROLD

MULTIPLE PRIMARY GROWTHS

SIR,—For a patient to have three primary growths removed from different organs all in one year must be uncommon

A woman, aged 62, was admitted to Hackney Hospital on Jan 19 1956, with a two-month history suggestive of pyloric stenosis Barium meal examination confirmed this, and at laparotomy on Jan 27 a mobile carcinoma of the pyloric antrum was found with no apparent local or distal spread. In addition there was a mobile carcinoma of the cæcum Partial gastrectomy was undertaken but owing to the patient s poor general condition it was decided to remove the cæcal growth later

Convalescence was protracted and it was not until March that she was regarded as fit for further operation On March 9 right hemicolectomy was undertaken and bowel continuity was restored by an end to side anastomosis. On this occasion, as previously no abnormality was found in the pelvis. Convalescence was uneventful and she was discharged on April 25

On Aug 23 she attended the surgical outpatient clinic complaining of slight loss of blood per vaginam twice during the past three months On examination there were no abnormal physical signs but dilatation and curettage on Sept. 14 showed a well differentiated adenocarcinoma. On Sept. 28 total hysterectomy and bilateral salpingo-oöphorectomy was undertaken The uterus showed a raised ulcerated area $^1/_2$ × $^1/_2$ in on the posterior wall of the fundus with no extension to the peritoneum or myometrium

The patient s convalescence was uneventful and she was discharged on Oct 22 When last seen as an outpatient on Nov 15 she appeared quite well having no trouble with her bowels and an excellent appetite

The relevant pathological reports were as follows

Stomach—An irregular prepyloric ulcer 9 × 6 cm. with hard edges, microscopically a moderately well differentiated adenocarcinoma with few mitoses.

Cæcum—An ulcerating growth 3 × 4 cm reaching the serosal surface apparently involving no glands: microscopically a poorly differentiated adenocarcinoma not extending to the serosal surface in the portion examined

Uterus—A thickened area of endometrium near the fundus 1 5 cm in diameter, microscopically, a well-differentiated adenocarcinoma

Hackney Hospital London E.9 **R F READ**

"DOCTOR"

SIR,—Your leading article of Feb 16 does not do justice to the spirit of the quotation with which it closes. Whether a man "thinketh in his heart" that he is a doctor or a physician and surgeon or a medical officer will not I think, be likely to affect what he is The surgeon who prefers to be called "Mister" may recognise. in his heart that he can assume no higher title than that of a man

Enfield, Middlesex **C M SMALL.**

ACUTE POLYNEURITIS TREATED WITH CORTISONE

SIR—Following upon the report by Dr. Graveson (Feb 16) of the successful use of cortisone in acute polyneuritis, it may be of interest to record an example of serum neuritis which quickly resolved following prednisone therapy.

The patient, a man aged 37, injured his thumb and was given an injection of anti-tetanus serum on the next day Eight days after the inoculation he had an acute systemic reaction with fever, generalised body pains, and a diffuse erythematous macular rash which lasted twenty-four hours. The generalised body pains cleared in two days but severe pain persisted in the right shoulder, and the musculature of the shoulder girdle especially the deltoid was very weak The C.S.F obtained by lumbar puncture showed: cells 17 per c.mm protein 90 mg per 100 ml, globulin ——, and Lange 1223330000 Oral prednisone 5 mg six-hourly was prescribed Within a day the pain had cleared Muscular power returned to almost normal in ten days. The dosage of prednisone was tapered off and discontinued after three weeks. A repeat of the C.S.F examination ten days after the original lumbar puncture revealed: cells 5 per c.mm, protein 50 mg per 100 ml globulin —, and Lange 1110000000

The concept of acute polyneuritis as an allergic manifestation and the general agreement that neurological sequels of serum therapy have a similar basis[1] suggest that steroid therapy promptly administered may prevent irreversible damage in serum neuropathy.

HEAD INJURIES

SIR,—Mr. T G. Lowden (Jan 12), writing about patients with head injuries admitted to peripheral hospitals asks "what should guide us in deciding whether to send on a case, to ask a neurosurgeon out to see it, or to get on with it ourselves" May I suggest that there is one kind of case which the local surgeon *should* get on with himself It is the patient who sustains a head injury without impairment of consciousness or with only momentary impairment who is apparently well for an hour or so, and who then complains of headache *or* vomits *or* becomes drowsy *or* exhibits any neurological sign Such a sequence must suggest an extradural hæmorrhage and there is no time to transfer the patient or to summon a neurosurgeon Many fruitless journeys into the country have convinced me that the local surgeon must assume responsibility for such cases. He may be diffident in tackling them for two reasons (1) he feels that he has not enough neurological experience to be sure of the diagnosis (2) he is unfamiliar with the operative technique May I point out that the clinical diagnosis is certain only when the patient is near death The only way to make certain before that stage is to make an exploratory burr-hole The rule is a burr hole on suspicion an operation when the suspicion is confirmed If the surgeon looks on a burr-hole as a purely diagnostic procedure not as an operation he will be much more likely to tackle these cases early The surgical technique necessary for dealing with a middle meningeal hæmorrhage could be acquired by any general surgeon who takes a week off to loiter in a neurosurgical centre When

---

[1] *Brit med J* 1956 i 972

patients who were unconscious on admission develop signs of compression of the brain, urgency calls for the local surgeon rather than the consultant

Dublin A A McCONNELL

DIHYDROCODEINE

SIR,—Respiratory depression has long been considered an unfortunate but inevitable effect of potent narcotics The recent report by Beecher and his colleagues[1] that *dihydrocodeine bitartrate produces full analgesia* while sparing the respiratory exchange has therefore aroused considerable interest

Having recently studied the effects of pethidine on the respiration in anæsthetised patients,[2] I decided to investigate dihydrocodeine under similar conditions Using the standards of equivalency of Gravenstein et al[1] and Nathan,[3] dihydrocodeine 0 25 mg per kg body-weight has been taken as approximately equivalent to the pethidine 0 6 mg per kg body weight used in the previous (control) study[2] There is no previous report of the intravenous use of dihydrocodeine, and in view of its pronounced acidity a dilute solution has been employed and the injection made slowly

First Study

The first investigation was carried out on twenty patients who were about to undergo surgical operation As in the pethidine series the patients were all in good general condition and were aged 20–50 The preparation of the patient and experimental technique have been reported elsewhere[4]

Briefly, anæsthesia was induced with 5% sodium thiopentone 8 mg per kg body-weight injected intravenously in 45 seconds, and nitrous oxide and oxygen (3 1) was then administered throughout the experiment via a closed circuit Respiratory rate and minute volume (M V) were measured 5 minutes after starting the thiopentone injection At the end of this (control) reading—i e , at 0+6 minutes—dihydrocodeine in standard dilution (25 mg per 10 ml) and standard dosage (0 25 mg per kg body weight) was injected intravenously in 30 seconds The respiratory rate and M V were measured 3, 5, 7, and 9 minutes after the administration of dihydrocodeine

About 1 minute after the injection of dihydrocodeine four patients began to move either one or both arms and/or legs, sometimes quite forcibly This movement continued for ½–2 minutes after which the patient became settled This phenomenon never occurred in the pethidine series In two patients there was localised reddening and wealing at the site of injection Neither of these effects was noted by Gravenstein et al[1] No other side effects were seen

Table I shows that dihydrocodeine produced, in mild degree, the typical effects of a narcotic analgesic Comparing its effects with those of pethidine (after checking with the F test of variance that the two groups come from a homogeneous population) the difference between the respiratory rates at corresponding times is significant at $p<0\ 005$, and the difference between corresponding M V s is significant at $p<0\ 005$ (except at 7 min $p<0\ 01$) In five patients there was virtually no depression of M V , in three there was a fall of more than twice the group average M V depression

TABLE I—RESPIRATORY CHANGES AFTER PETHIDINE 0 6 MG PER KG AND DIHYDROCODEINE 0 25 MG PER KG

Feature	Series	Control	3 min	5 min	7 min	9 min
Respiratory rate (min)	Pethidine (S E ±)	10 1 *(0 8)*	10 6 *(1 0)*	9 9 *(1 1)*	10 1 *(1 0)*	9 2 *(0 6)*
	Dihydrocodeine (S E ±)	18 3 *(0 7)*	15 2 *(0 7)*	14 4 *(0 7)*	14 0 *(0 7)*	13 8 *(0 7)*
Minute volume (ml)	Pethidine (S E ±)	5361 *(400)*	3260 *(353)*	3318 *(409)*	3618 *(414)*	3129 *(327)*
	Dihydrocodeine (S E ±)	5129 *(311)*	4075 *(307)*	4985 *(295)*	5081 *(232)*	4912 *(263)*
% change in minute alveolar ventilation	Pethidine		−32 4	−20 7	−0 7	−2 1
	Dihydrocodeine		−0 6	+7 3	+11 0	−7 5

Second Study

This superiority of dihydrocodeine over pethidine in respect of respiratory depression may be intrinsic, but it could be because this dose of the drug is not, in fact, equipotent with pethidine 0 6 mg per kg body weight Accordingly the experiment was repeated in a further twenty patients using twice the dose of dihydrocodeine, the solution was of twice the concentration Furthermore it was decided to try the antagonistic effect of levallorphan tartrate in any cases where appreciable respiratory depression occurred

The "stimulating" effect mentioned above was seen in three cases Local wealing and reddening occurred in five patients Linear wealing along part or the whole length of the injected vein was noted in six cases

Table II gives the respiratory changes in this group of patients Statistical comparison with the pethidine series shows that the mean *fall* in respiratory rate is significantly less ($p<0\ 025$) and the mean M V significantly greater ($p<0\ 05$) in the dihydrocodeine group In three cases there was virtually no fall in M V , in two the M V depression was more than twice the group average

TABLE II—RESPIRATORY CHANGES AFTER DIHYDROCODEINE 0 5 MG PER KG

Feature	Control	3 min	5 min	7 min	9 min
Respiratory rate (min) (S E ±)	15 5 *(0 9)*	14 6 *(1 0)*	13 6 *(1 0)*	13 4 *(0 8)*	13 0 *(0 8)*
Minute volume (ml) (S E ±)	5141 *(305)*	4644 *(355)*	4470 *(286)*	4613 *(308)*	4601 *(293)*
% change in minute alveolar ventilation		−3 8	−3 0	+5 3	+7 2

Levallorphan was injected intravenously 10 minutes after the dihydrocodeine and readings of the respiratory rate and volume were taken 1, 3, and 5 minutes later As in two patients a 1 100 ratio of the two drugs proved ineffective, a 1 50 ratio was tried This has been employed in nine cases and has been found consistently to produce an immediate and pronounced increase in M V and some increase in rate

Comment

Investigation of dihydrocodeine under the present conditions will exaggerate the drug's respiratory depressant effect because of an additive effect with thiopentone[5] However, comparison with the effects of pethidine under identical conditions shows that dihydrocodeine depresses respiration considerably less even in apparently more than equipotent dosage

The results suggest that further clinical studies of dihydrocodeine's analgesic potency would be worth while Although this drug does not appear to produce appreciable respiratory depression in clinical dosage it is valuable to have an antidote available, and it seems likely that levallorphan will fill this need The initial "stimulating" and the histamine releasing properties of dihydrocodeine will require investigation

I am grateful to my surgical colleagues and to the theatre staffs of Salford Royal and Hope Hospitals for their cooperation, Mr Kenneth Spencer and Dr Randolph White for undertaking the statistical analysis, and Duncan, Flockhart & Co Ltd for providing the dihydrocodeine bitartrate

OLD PEOPLE IN HOSPITAL

SIR,—The articles in your last issue by Dr DeLargy and by Dr Rang raise an important question What principle should guide us in admitting elderly patients to hospital? The waiting list of most geriatric units contains the names of some who are likely to respond to medical treatment but of many others who are not Dr DeLargy's scheme of a six-week stay in hospital is a valiant attempt to meet the needs of the latter My own survey in Croydon[1] demonstrated that the majority of elderly patients have some social problem complicating their medical condition Even though they may recover from the illness which precipitated admission to hospital, they may not be able to return whence they came Yet there are many others anxiously awaiting the use of the bed they occupy

I have found that in such cases transfer to a "halfway house" is helpful The frail ambulant can here continue with some treatment and rehabilitation while a solution to their social problems is sought I am somewhat disturbed, therefore, to read that the average length of stay in the "halfway house" for Dr Rang's unit is measured in years rather than weeks My own turnover has been 3 per week (out of a total of 24 beds) for several years past

My greatest perplexity arises over the mass of incurable patients who tend to silt up the beds in my hospital wards Some have been transferred from general hospitals to free acute beds there, some have been admitted as social emergencies to prevent further suffering in unsuitable surroundings, and some are simply unlikely to respond to medical treatment It is these patients, not those in the "halfway house," whose length of stay tends to be measured in years rather than weeks It is these whose relatives have so far been unwilling to take them home to nurse them there It is these cases whose mere existence prolongs the waiting-list and delays admissions

The number of aged sick, increasing year by year, grows faster than the number of staffed hospital beds available for their treatment, care, or custody Hence Dr DeLargy's scheme has a great deal to commend it for trial For, if there is delay in admitting patients with social complications, a state of urgency is likely to arise Yet, if such cases are given priority, the length of the waiting list and average duration of stay in hospital increases Let us hope that the Langthorne procedure will be the via media out of this impasse

London S W 16 TREVOR H HOWELL

MUNCHAUSEN'S SYNDROME

SIR,—It may be useful to report another case of Munchausen's syndrome who has been turning up at London hospitals over the past few years

Usually he simulates meningitis or subarachnoid hæmorrhage, but his repertoire has also included tetanic spasms as well as the usual abdominal components of the syndrome Our first record of him dates from December, 1953, when he was admitted to Guy's Hospital with abdominal pain and hæmatemesis, but laparotomy showed no abnormality He has five abdominal scars in all The following year he was admitted to both Putney Hospital and Guy's Hospital with symptoms suggesting tetanus In 1955 he apparently attended many hospitals, including Guy's, St Thomas's St Bartholomew's, St George's, St Pancras, Poplar General, North Middlesex and this hospital He was seen in several psychiatric outpatient departments but never kept his further appointments His symptoms included abdominal pain, suicidal impulses and neck stiffness In December, 1956 he attended Guy's Hospital with neck stiffness, photophobia and headache, he was admitted but discharged when nothing abnormal was found A week later he was admitted to the West London Hospital again with feigned meningitis He discharged himself on Jan 16 and the same afternoon was admitted to St Mary's Hospital complaining of the sudden onset of headache, stiff neck, and photophobia Lumbar puncture yielded normal cerebrospinal fluid, and after two days he began to have spasms of opisthotonos with flexion of one arm and leg On being confronted with the evidence of his previous hospital admissions, and with the news that his father was coming to see him, he immediately recovered and was discharged

It seems highly probable that he will turn up at other hospitals over the next few years, and this information may help to identify him

St Mary's Hospital,
London, W 2 P H SANDERSON

ALLOXAN AS A POSSIBLE THERAPEUTIC AGENT FOR PRIMARY CARCINOMA OF THE LIVER

SIR,—Laboratory observations by others that alloxan-diabetic rats are either totally resistant to the experimental induction of hepatomas by feeding azo dyes, or can suppress the growth of tumour implants, prompted Professor Gillman and his colleagues (Jan 12) to administer alloxan to patients with advanced hepatomas in an attempt to induce diabetes and to influence the tumour Although their results in 4 cases were rather doubtful in regard to the effect of alloxan on the blood sugar and on the course of the malignant disease, they conclude that the "findings provide some basis for recommending further and more extensive investigation of the significance and interactions of alloxan injections on cancers "

The authors are apparently unaware that such investigations were carried out more than ten years ago shortly after the discovery of the diabetogenic action of alloxan[1–3] They were terminated because of rather deleterious results In a small group of patients with far-advanced carcinoma of various organs with and without liver metastases, alloxan failed to induce diabetes but precipitated severe hepatorenal damage with jaundice and hepatic coma Also, in insulinomas no satisfactory control of the hypoglycæmia could be obtained but severe liver damage occurred Histological examinations in these cases demonstrated no significant effect on either the pancreatic beta cells or the tumour tissue but destruction of renal and hepatic parenchyma It appeared that in man, unlike most laboratory animals, the hepatotoxic and nephrotoxic dose of alloxan is smaller than the diabetogenic dose

While Professor Gillman and his colleagues observed no aggravation of the liver disease, they too failed to obtain hyperglycæmia and glycosuria I would feel negligent if I did not recall these earlier observations and caution against the use of alloxan in man even in conditions which are presently incurable and usually fatal

Brooklyn 3, New York MARTIN G GOLDNER

RADIOACTIVE VITAMIN B_{12} IN THE DIAGNOSIS OF NEUROLOGICAL DISORDERS

SIR,—The informed comments of Dr Booth and Dr Mollin relating to radioactive vitamin B_{12} (Feb 16) are most welcome in underlining important theoretical points relating to physiological and pathological aspects of vitamin B_{12} utilisation

May we re-emphasise the practical clinical importance of the excretion test and in particular of the second part of the test in establishing a diagnosis of subacute combined degeneration of the spinal cord? If with the Schilling excretion test a normal result is obtained after

RESOLUTIONS BY JUNIOR HOSPITAL STAFF

ON Feb 11 at a meeting of the junior medical staff of the Edgware General Hospital, the following resolutions were passed unanimously

We shall support to our utmost every effort to secure the 24% increase in remuneration being sought by the Negotiating Committee At the same time we wish to draw especial attention to the urgent needs of full time junior hospital staff, whose salaries are entirely inadequate and who need more than a 24% increase on their present salaries to bring them to a reasonable standard of remuneration

Further it is agreed that the present claim and past increase in salary in no way detract from our belief that the Spens report concerning the remuneration of hospital staff must finally be implemented, as this has not hitherto been done

It is also resolved that a mere increase in salary is not sufficient nd that prospects of promotion must also be improved. At present he prospects of promotion for those wishing to specialise are irtually non-existent, and to this end a complete revision of the taffing of hospitals is urgently required

CHILDREN'S INSTITUTIONS

TODAY it is widely accepted that an institution is one of the less satisfactory places in which to bring up a child But unfortunately there will always be some children who, usually for unhappy reasons, must spend a shorter or longer part of their childhood in an institution It is therefore important that the place should not be as forbidding as the name and that the care it offers should be the best that can be arranged. A report to the Social Commission of the United Nations[1] reviews institutions and new work in countries all over the world A global survey of only 70 pages must be selective, but this one makes clear that, though the diversity of their practice sensibly reflects local customs and conditions, the nations share a common concern for these vulnerable children

MALARIA CONTROL

LAST November delegates from many countries in Africa and islands in the Indian Ocean met in Nairobi under the auspices of the World Health Organisation, to discuss malaria control South Africa, Mauritius and the higher parts of Southern Rhodesia and Madagascar are now (it was reported) virtually free of the disease the control campaigns will be continued till malaria has become a curiosity—which is already true in Mauritius In West Africa success is described by Dr M T Gillies as only occasionally great enough to justify the large sums of money spent on it, "The fact that it is only partially successful," he says, "means that the spraying must be continued indefinitely It is here that the danger lies In Northern Nigeria a trial project was carried out using one of the newer insecticides The results were so encouraging the first year that plans were made for a very large scale extension of the scheme so as to protect eventually up to two and a half million people But during the second year the mosquitoes began to come back again into the houses, and it was soon discovered that they had become resistant to the insecticide and were no longer being killed by it When I was there in July 1956 the position was so bad, and the mosquitoes so numerous, that in the evenings the toads would gather about the verandah floor and pick off the *Anopheles* from our shoes and ankles as they settled there to bite In fact it was perfectly clear that control with this insecticide had completely broken down and the whole campaign had to be switched to another insecticide which remains, for the moment, moderately successful This unhappy experience has up till now only been repeated in one other area, also in Northern Nigeria But its occurrence is the writing on the wall. It is now realised that in regions where resistance is likely to occur, we have only a few years in which to eliminate malaria before the weapons become blunted in our hands We do not know at present how widespread the tendency to develop resistance is but it is encouraging that it has not appeared in South Africa despite the use of insecticides for up to ten years"

Air-conditioning for Bronchitis

A scheme is being prepared for air conditioning two wards at the Liverpool Chest Hospital so that the effect of nursing chronic bronchitics in such accommodation during severe winter weather and fog can be studied.

University of Leeds

Dr G H. Lathe has been appointed professor and head of the department of chemical pathology

Dr Lathe who is 43 years of age graduated B.Sc in 1934 from McGill University, Montreal, and M D four years later After holding research appointments in the department of physiology he served from 1941 to 1945 as a regimental medical officer and later as a biochemist in the Royal Canadian Army Medical Corps In 1946 he came to England and held an I C I research fellowship at the University of Oxford and at the Postgraduate Medical School of London. In 1947 he was awarded the degree of PH D of McGill University Since 1949 he has held the post of biochemist in the Bernhard Baron Chemical Research Laboratories of Queen Charlotte's Maternity Hospital, London, and he is a member of the academic board of the Institute of Obstetrics and Gynaecology He has published articles on absorption from the alimentary tract, the physiological and metabolic consequences of wounds, and the biochemistry of the bile pigments and their production in the liver

Dr J M Roberts has been appointed lecturer in the department of psychiatry.

University of Otago

Dr J R Robinson, assistant director of research in the department of experimental medicine of the University of Cambridge, has been appointed associate professor of physiology in the university

Dr Robinson, who is 42 was educated at Ulverston Grammar School and Emmanuel College, Cambridge He took a double first in the natural sciences tripos and after graduating spent some years while holding the research scholarship of his college, in the departments of biochemistry and colloid science studying the shapes of protein particles in solution. In 1938 he took the degree of PH D and in 1940 he went to the London Hospital Medical College with an open entrance scholarship After qualifying in 1943 he held house appointments at the London and in 1944 he joined the R.A.M.C and served in India, where he was in charge of the biochemical department of the central military pathological laboratory at Poona In 1947, after he returned to civilian life, he was appointed college lecturer and director of studies in medicine at Emmanuel College and was elected to a supernumerary fellowship He was appointed to his present post in the department of experimental medicine in 1949, and since 1951 he has also been secretary to the faculty board of medicine He received the degree of M D in 1952 He spent 1954–55 in New Zealand as a senior visiting lecturer in the department of physiology of the University of Otago His published work includes papers on electrolytes and renal function.

University College of the West Indies

Dr R J Gourlay, assistant senior medical officer of the North West Metropolitan Regional Hospital Board, has been appointed senior lecturer in preventive medicine

Harveian Society of London

Sir Russell Brain, P R C P, will deliver the Harveian lecture to this society on Wednesday, March 27, at 8 15 P.M, at 11, Chandos Street, London, W 1 He is to speak on disorders of the cerebral circulation

British Diabetic Association

The Banting memorial meeting of this association will be held in Oxford on July 12 and 13 The speakers will include Prof H A Krebs, F R.S, and Prof C H Best, F.R S Further particulars may be had from the association, 152, Harley Street, London, W 1

Association of Surgeons of Great Britain and Ireland

The annual general meeting of this association will be held at Newcastle upon Tyne from April 25 to 27 Prof Alexander Haddow will give the Rutherford Morison lecture on the present trends of cancer research, and the programme will also include discussions on prevention of sepsis in operating-theatres (opening speakers Mr D R Davies Dr R Blowers, and Dr R A Shooter), minor complaints of the rectum and anus (Mr T McW Millar, Mr A G Parks, Mr H T Simmons, and Mr H R Thompson), early treatment of burns (Mr A B Wallace), and thyrotoxicosis (Dr W R Trotter and Mr K Paterson-Brown)

A Comprehensive Nursing Course

In September an experimental course is to be started by the Postgraduate Medical School of London, the Battersea College of Technology, and the Queen's Institute of District Nursing which will enable a student in 4 years, instead of the present 5 years or more, to qualify as a State registered nurse, a health visitor, and a Queen's district nurse She will be able to take a part I Central Midwives Board certificate, so that with only 6 months' further training she can also become a fully qualified S C M Previously the course for each of these examinations has had to be taken separately

---

[1] Institutional Care of Children (United Nations Department of Economic and Social Affairs 1956 Obtainable from H.M Stationery Office Pp 70 3s 6d)

Newcastle Flying Squad

The 21st birthday of the Newcastle Obstetric Emergency Service, whose work was described in an annotation last week, was celebrated on Feb 21 when a party was given at the Princess Mary Maternity Hospital by the board of governors of the United Newcastle upon Tyne Hospitals Viscountess Ridley, chairman of the committee of management of the Princess Mary Maternity Hospital, presented a portrait to Prof E Farquhar Murray, who was largely responsible for the inauguration of the service

Nutrition Society

This society is holding a symposium at 1, Wimpole Street, London, W 1, on Saturday, March 23, on Man's Need for Water Prof R A McCance, F R S, will be in the chair and the speakers will include Mr H W Cremer, F R I C, Dr J R Robinson, Dr J Russell Elkinton, Miss E M Widdowson, D SC, Dr D A K Black, and Dr W F Young Further particulars may be had from the hon programmes secretary of the society, Dr R J L Allen, c/o Beecham Foods Ltd, Brentford, Middlesex

Scottish Group—This group is holding a symposium in Aberdeen on Saturday, April 20, on clean food Further particulars may be had from Dr J Davidson, Rowett Research Institute, Bucksburn, Aberdeenshire

Revised Fees for Dentists

Changes in the fees payable to dentists for treatment under the National Health Service will come into force on April 1 The revised scale, which has been drawn up in consultation with the British Dental Association, is not designed to give an increase in the total remuneration of dentists but rather to achieve a better balance

More money is being devoted to the treatment of children's teeth, and in place of the present flat fee applying to any conservative treatment to a deciduous tooth varying amounts will be payable for different kinds of fillings, for vital pulpotomy, and for conservation by other means The removal of calculus, the removal of stain and polishing of the teeth also attract separate fees These changes will it is hoped offer further encouragement to the treatment of young people

Crash Helmets

On and after April 1 it will be an offence to sell, or offer for sale, a protective helmet for motor cyclists unless it is of a type authorised by Ministry of Transport regulations

Lipids and the Problem of Atherosclerosis

Prof R A Morton, F R S, will give an address on this subject to the Oils and Fats Group of the Society of Chemical Industry on Wednesday, March 13, at 7 P M, at the department of organic chemistry of the University of Liverpool

The Child and his Home

The British Social Biology Council is holding a summer school on this theme, for teachers, social workers, health visitors, and others, at Aix en Provence from Aug 24 to Sept 8 Further information can be had from the council, Tavistock House South, Tavistock Square, London, W C 1

Glasgow's Tuberculosis Campaign

To mark the opening of this campaign, Sir Geoffrey Todd is to give a lecture at the Institution of Engineers and Ship Builders, 39, Elmbank Crescent, Glasgow, C 2 on Wednesday, March 13, at 4 P M He is to speak on the prognosis of pulmonary tuberculosis in the light of modern treatment, with special reference to Midhurst Sanatorium

Ocular Manifestations in Clinical Neurology

Mr Joseph Minton will give six lecture demonstrations on this subject at the West End Hospital for Neurology and Neurosurgery, 91, Dean Street, London, W 1, on Tuesdays at 4 P M, beginning on April 9 Further particulars may be had from the secretary of the postgraduate medical school of the hospital

Dr Frank Falkner has been awarded a scholarship in medicine of the John and Mary Markle Foundation

The Tanner prize of the Royal Institute of Public Health and Hygiene for 1956 has been awarded to Dr Sheila Robinson

CONSULTANT PHYSICIAN TO THE HERTFORD GROUP OF HOSPITALS, MEDICAL CHIEF ASSISTANT, THE GORDON HOSPITAL

Knowledge of the natural history of ulcerative colitis is necessary in assessing prognosis It is also important in deciding whether the treatment of a particular patient should be medical or surgical The majority of patients suffering from ulcerative colitis run an unpredictable course, and in these the decision whether to advise removal of the colon is often very difficult It was thought that some help might be gained by reviewing very briefly our personal experience of a large number of patients in one hospital

The natural history of the following series of patients illustrates the difficulty of forecasting the outcome, in most patients, from the previous course of the disease It also shows that those with a poor outcome did have certain common features which may assist in achieving earlier an accurate prognosis in future patients

The prevalence of ulcerative colitis in the population is difficult to estimate In 1946 one of us (E R C) admitted to hospital every patient who came complaining of chronic diarrhœa Of 99 consecutive cases, 41 were found to be of ulcerative colitis (Cullinan 1949)

Material

The material consists of 346 patients about whom we have up-to date information who first attended the Gordon Hospital, London, between July 1, 1947, and June 30, 1955—i e, exactly eight years. The series includes both "medical" and "surgical" cases 170 of the patients were under the personal care of one of us (E R C), the remainder were under the care of our surgical colleagues, and the majority were seen by one or both of us The figures are derived from a continuous follow-up which is being carried out by one of us (I P M.)

The few cases of regional and segmental colitis and those whose diagnosis was in doubt have been deliberately omitted The cases have been divided into three arbitrary groups according to the extent of colon involved

Group A (diffuse)—Those with evidence of involvement of the entire colon

Group B (distal)—Those with evidence of involvement of part of the colon continuous distally to the rectum

Group C—Those with sigmoidoscopic evidence of ulcerative colitis but negative X-ray findings

The division was made because, as will be shown, the severity and gravity of the disease differs markedly in the three groups Our justification for regarding these three groups as different degrees of the same disease process is that the sigmoidoscopic appearances were the same in all and the histological findings in rectal biopsies were identical (Lumb and Protheroe 1955) For example, in group C the 68 patients all underwent sigmoidoscopy 26 were selected at random for biopsy and 21 of these had histological findings indistinguishable from those of the patients in the other groups This does not prove the point, but the argument is reinforced by a further fact Besides the 68 patients who were "X-ray negative" at the last examination, 20 who were in this category when first seen later became "X-ray positive," 11 finally having the entire colon affected

We have seen 12 patients first recognised as being in group B (with the so-called "distal" colitis) later develop "diffuse" colitis (group A) It should be remarked that these changes were independent of the duration of the disease

TABLE I—DISTRIBUTION ACCORDING TO SEX AND EXTENT OF DISEASED COLON AT THE LAST EXAMINATION

—	Group		
	A	B	C
Male	53	57	24
Female	80	88	44
Total	133 (*38*%)	145 (*42*%)	68 (*20*%)

Table I shows the number of patients in each group at the time of the last examination

Table II shows the age at onset of symptoms, which ranged from 4 to 90 The great majority began between the ages of 20 and 50 In all groups women preponderate over men in the ratio of 60 40 There was no significant difference in the age at onset in the three groups

History

Previous History

The former health of the patients had been good There was no previous history of colonic disorders such as the syndrome of "irritable colon" Only 3 patients had a family history of the disease

TABLE II—AGE AT ONSET OF SYMPTOMS

Age		0–9	10–19	20–29	30–39	40–49	50–59	60–69	70–79	80–89	90	Total
No in all three groups	Male	2	12	33	30	36	12	4	4	0	1	134(*39*%)
	Female	3	21	63	54	34	18	16	2	1	0	212(*61*%)
	Total	5	33	96	84	70	30	20	6	1	1	346

Onset

The onset of symptoms was more often abrupt than gradual In each group the initial degree of illness was seldom severe, although early deterioration in some of the patients was rapid

Cause of the onset—We do not intend to discuss ætiological factors in ulcerative colitis, but must mention two We were again impressed by the importance of psychogenic factors in the ætiology, though their mechanism remains obscure Their recognition, although not calling for specialised psychotherapy, is most important for successful treatment

Another factor which demands explanation is the effect of pregnancy One of us (I P M) found that of the 100 women in this series who had been pregnant, a quarter ascribed the onset of the disease to pregnancy or the puerperium (MacDougall 1956)

Subsequent Course of the Disease

Those patients whose course was predictable from the onset were few Only 2 ran so violently acute and fulminant a course (with profuse and severe diarrhœa and the passage of blood, pus, and mucus, accompanied by grave constitutional illness starting within a few hours or days of the onset) that they would almost certainly die within days or weeks (usually of general peritonitis following perforation) Only 27 had unremitting severe symptoms, and only 11 were predictable in the sense

TABLE III—DURATION OF SYMPTOMS TO DATE, TO OPERATION, OR TO DEATH (ALL 3 GROUPS)

Duration (yr)	<1	1–5	6–10	11–15	16–20	21–25	26–30	31–35	36–40	>40
No of patients	18	99	120	62	34	15	9	2	3	2

that they had annual or biannual relapses with persistent regularity The remaining 306 cases ran an unpredictable chronic course, often lasting for many years, marked by remission and relapse

Table III shows the duration of the disease to date, to operation, or to death It will be seen that about 70% of the cases have already lasted for over five years and that some have lasted for over thirty years

The mode and severity of the onset bore little relation to the subsequent behaviour of the illness and the most banal beginnings sometimes had very serious later developments In most cases the lengths of remissions and the severity of relapses were unpredictable We have carefully compared the course of the disease before the patient first attended for treatment with its subsequent behaviour and have found so little correlation that this is seldom of value

Mortality

The gravity of the attack and of the relapses, however, is very *different in the three groups* The *greatest* danger to life and the greatest severity of symptoms is, as would be expected, in group A where the entire colon is affected The danger to life in the three groups is shown in table IV

TABLE IV—MORTALITY (INCLUDING PATIENTS OPERATED ON) RELATED TO EXTENT OF COLON INVOLVED

—	Group			All groups
	A	B	C	
No of patients	133	145	68	346
No dead	20	8	0	28
Percentage dead	15	5 5	0	8

The disease in groups A and B was roughly comparable in duration, but it will be seen that there were three times more deaths in group A than in group B In group C the illness is non fatal 31 patients in group A showed involvement of the terminal ileum The mortality was the same in these as in the remainder of the group

Severity

The severity of symptoms of the initial attack and of relapses is directly related to the extent of colon involved

In group A (the diffuse type) the patient may gradually or suddenly become extremely ill There may be high fever, profound exhaustion, dehydration, toxicity, and extreme emaciation Severe diarrhœa is the rule

In group B (the distal type) the initial active phase and the relapses are usually associated with far less general upset and are characterised more by bleeding and anæmia There may be either diarrhœa or constipation

In group C, bleeding is usually the only symptom Occasionally there is a *little mild fever* The patients are often constipated, though sometimes the stools are loose

These differences of severity are illustrated in table V, which shows the course of the disease after the attack which first brought the patient to the Gordon Hospital

It will be seen that over half the patients in group A suffered severe or very severe symptoms, that over half in group B were in virtually normal health, and that in group C there were no severe symptoms at all

Other Criteria

The *extent of colonic involvement* is a useful guide to the probable outcome, but the intensity, severity, and duration of the attacks is almost as important as the extent of bowel involved Toxæmia, malnutrition dehydration, leucocytosis, anæmia, and certain systemic complications are indications of severe and potentially lethal disease

"Systemic complications" included malnutrition, hypoproteinæmia, oral ulceration, glossitis and cheilosis, erythema nodosum and pyoderma, polyarthritis, thrombophlebitis, iridocyclitis threatening blindness, and peripheral neuritis

An analysis of the whole group, after excluding the 68 cases in group C, in which there have been no deaths, revealed that the majority of the severely ill and fatal cases showed two or more of the following three features leucocytosis of 10,000 or more cells per c mm , (2) hæmoglobin below 70% , and (3) one or more "systemic complications"

This "toxic triad," as one of us (I P M) has named it, is far less commonly seen in group B than in group A, 28% of patients in group A had 2 of the features and only 4% in group B *But it is interesting to observe, in* retrospect, the striking difference in mortality between patients with none or one and patients with *two* of the three elements of this triad, the latter being nearly nine times the former (table VI) This cannot, of course, be used as a rule of thumb, but it does show that signs of severe toxicity are of equal importance whether part or all the colon is diseased

Local Complications -

Many of the patients had local complications in the bowel but these were not connected with fatality to the same degree as the systemic complications They included severe hæmorrhage, perirectal and pericolic lesions, strictures, and pseudopolyposis, and often required operative treatment In parenthesis, it is interesting that in two patients who had developed recto vaginal fistulæ, the fistulæ healed spontaneously without operation 6 patients in the series developed malignant degeneration They were all patients in group A who had had the disease for a long time—2 for eight years and the others for thirteen, nineteen, twenty five, and twenty-six years The patient who had had symptoms for thirteen years was interesting the carcinoma developed in a functionless colon, an ileostomy having been done three years before

Treatment

Influence of Medical Treatment

We shall not discuss the treatment of ulcerative colitis but wish to make three comments

TABLE V—SYMPTOMS AFTER TREATMENT

Symptoms *	Patients with symptoms (% of group)		
	Group		
	A	B	C
None	11	20	41
Trivial	8	31	45
Moderate	11	17	13
Severe	22	9	0
Very severe	35	0	0
Insufficient information	11	11	1

* Explanation of severity of symptoms

None No symptoms since recovery from attack which brought patient to Gordon Hospital

Trivial Occasional loose stools or rectal bleeding, with long remissions Work and recreation not interfered with

Moderate Diarrhœa in attacks (bowel actions 3–5 times daily often with blood) Hospital admission sometimes required Disease is a handicap interfering with but not usually preventing work or recreation. Often long remissions

Severe Continuous diarrhœa (bowels opened 3–8 times daily often with blood) or attacks of greater severity but with periods of remission Many of these patients have been operated on

Very severe Fulminating or relentless disease, usually fatal if operation withheld

TABLE VI—MORTALITY-RATE RELATED TO THE "TOXIC TRIAD" (ANÆMIA, LEUCOCYTOSIS, SYSTEMIC COMPLICATIONS)

—	Group A	Group B	Total
Patients with two features	36%	33%	35%
Patients with one feature or none	7%	3 6%	4 2%

The first is that four cardinal needs are vital to success in the general medical treatment of ulcerative colitis and may be summarised as follows meticulous and patient nursing, unremitting care in alleviating symptoms as they arise, detailed *attention* to nutrition, fluid and electrolyte balance, and the like and courage, patience, encouragement, and quiet confidence and faith of physician and nurse which transmit themselves to the sufferer It is difficult to overemphasise these needs Lack of attention, and gloom and despair, can kill

We have had little success with chemotherapeutic and antibiotic agents We have found neomycin useful in sterilising the stool as a preoperative precaution, for helping an open lesion in the rectum or anus to heal, and in the violently acute fulminating cases where perforation threatens Otherwise we have found them of little or no value in treatment

Only certain patients responded satisfactorily to corticotrophin (A C T H) or cortisone—usually those who were having a severe acute attack, particularly in the earlier stages of the disease When they were effective, the results were striking, and sometimes led to a complete remission These effects were of great value as a prelude to surgical operation in critically ill patients

Surgical Treatment

Sometimes the decision to advise operation is easy Certain complications threatening early death or grave disability are clear indications for surgery Again, when the course of the disease is severe and predictable, as in the acute fulminating type, or when there are long-continued, unremitting, severe symptoms with relentless deterioration of the patient, in spite of efficient medical treatment, it would be folly to withhold colectomy

The majority of cases of ulcerative colitis, however, pursue an irregular and largely unpredictable course, and it is important to decide which of these patients should be advised to have surgical treatment There is little doubt that some patients die for want of a timely operation, but the opposite extreme of removing the colon in every case would be an absurd policy The decision as to which cases should be selected for surgery grows in importance as the operation for removal of the diseased colon becomes safer, but it is still not to be undertaken lightly However lyrical one becomes, there is nothing poetic about an ileostomy The development of operations to restore the continuity of the bowel after resection of the colon, though very encouraging, is still in its early days Each individual case has to be judged on its own merits, but the paragraphs which follow crystallise our present general view, supported, we think, by the figures we have shown

The clinical course in X-ray negative cases (group C) is mild so long as there is no proximal spread

The outlook in the majority of cases of the *distal type* of X ray positive cases (group B) is usually relatively benign, and such patients are not likely to require surgery except for the relief of certain local complications We are satisfied that most of these patients have *less disability* than they would after surgery This enables one to plan for the majority a conservative course *and to* give a reassuring prognosis We have *already shown* that half of them are, for all practical purposes, in normal health

If the whole colon is affected (group A) the disease commonly causes death or *invalidism*, and *operation* is much more likely to be needed, although a [illegible] number of such patients do well with medical management

It is our opinion that all patients with evidence of severe toxicity, as previously defined, have a potentially lethal disease and should have their colons removed Furthermore, if the long-term effects of operations to restore continuity of the bowel after resection of the colon prove satisfactory, we think we should probably advise all patients who have the diffuse type of ulcerative colitis (group A), and do not quickly improve with *medical* management, *to* have a colectomy, and this would be our advice until the day when this strange disorder can be cured by medical means alone

One of us (I P M) receives a grant from the Gordon Hospital (Westminster Hospital's teaching group) Research Fund We are grateful to our surgical colleagues at the Gordon Hospital for allowing us unrestricted access to their patients, and to Miss H M Davies, the research secretary, for her help

The treatment of *advanced mammary cancer* by modifying the endocrine *environment* may be said to have started in 1896, when *Beatson removed the ovaries* of two patients *with widespread metastases* and produced remissions *Lett reported a further series at a* meeting of the Royal *Medical* and Chirurgical Society in 1905, *and for many years subsequently oophorectomy* was *practised sporadically, resulting* in temporary improvement *in about a third of the patients*

Evidence that ovarian hormones are concerned in the *production of carcinoma* of the breast has since been *provided* by experiments on animals, notably those *of Lacassagne (1932), who* induced malignant changes in the *breasts* of male mice by injecting large amounts of *œstrone benzoate* Furthermore in recent years [illegible] instances have been recorded of carcinoma of the [illegible] developing in male patients who had received [illegible] of œstrogens for prostatic carcinoma (Graves and [illegible] *1952*)

While oophorectomy represented an [illegible] treatment of widespread breast cancer [illegible] obtained posed new problems, because [illegible] patients responded and even in the [illegible] benefit was temporary An explanation [illegible] in the secretion of œstrogens by [illegible]

would be unaffected by the removal of the ovaries In 1945 Huggins performed adrenalectomy on patients with advanced disease, but they all afterwards died of adrenal failure, and the results were not reported until later (Huggins and Dao 1953)

Independently in this country, the first adrenalectomy for breast cancer was performed in November, 1947, by one of us (H J B A) at Guy's Hospital The object was to remove as much as possible of œstrogen secreting tissue, but, as cortisone was not available at that time, it was not possible to perform total adrenalectomy Both ovaries and about three-quarters of the left adrenal gland were removed at the first stage, and the whole right adrenal gland at the second stage Seven such cases of advanced breast cancer were operated on in this way, 'Eschatin,' 'Eucortone,' and deoxycortone acetate being used as supportive therapy for about 5 days after the second operation until the surviving fragment of the left adrenal resumed its function There was one postoperative death, and two cases showed slight remission These cases, also, were not reported, because it was thought that, if enough adrenal tissue were removed to affect the cancer significantly, the hazard to life would be too great, and the method was allowed to lapse

With the advent of cortisone, however, total adrenalectomy became a practical proposition, and, following the lead of Huggins, a fresh start was made at Guy's Hospital By November, 1953, when hypophysectomy was introduced as an alternative method of treatment, eighteen cases of advanced breast cancer had been subjected to oophorectomy and total adrenalectomy in two stages, and this had become a standard procedure for patients with inoperable growths who were unsuitable for radiotherapy and had not responded to hormones

Although total adrenalectomy with oophorectomy proved more effective than oophorectomy alone, there was the same inconsistency in the results On the assumption that the failures and relapses might be due either to aberrant adrenal tissue, which could be controlled by removal of the pituitary gland, or possibly to a carcinotrophic substance secreted by the pituitary itself, hypophysectomy became the next logical step Encouraging results were reported by Luft and Olivecrona (1953), and the first hypophysectomy for breast cancer was done at Guy's Hospital in November, 1953, by one of us (M A F)

From the first reports it was obvious that hypophysectomy was not going to provide the final answer to metastasising carcinoma of the breast Many patients still did not respond, and others relapsed after initial improvement The question whether hypophysectomy offered any clear advantage over total adrenalectomy with oophorectomy was obviously therefore of great importance, and it is with this question that the present investigation was concerned

Selection of Cases

During the past 3 years adrenalectomy or hypophysectomy has been considered for all patients with advanced cancer of the breast for whom the possibilities of direct surgery irradiation, and hormone therapy have been exhausted Cases in this category were to be discarded only if they were regarded as quite unsuitable for any operation, the patients being moribund Only one case has, in the event, been discarded on such grounds—because of multiple secondary deposits in both lungs and extreme dyspnœa at rest In another case, which was selected for hypophysectomy, the patient died of the disease before the operation could be undertaken

A few patients have been left out of the series because they or their doctors specified which of the two operations should be performed In the remainder, comprising the sixty here reviewed, the type of operation was decided by a method of random selection which is accepted as precluding bias towards one operation or the other (Atkins 1956)

Technique of Adrenalectomy

Preoperative

The patient is admitted to hospital 3 days before operation, so that a final check can be made on the stage which the disease has reached Visible or palpable lumps are again measured, and fresh X-ray photographs are taken of bone or chest lesions Hæmoglobin is estimated and samples of urine are taken for analysis of the 17 keto steroids (see accompanying paper Allen et al (1957))

Cortisone is given in preparation for the first stage, because, if one adrenal has been destroyed by growth, removal of the other will deprive the patient of all her adrenal tissue

Since preoperative preparation with cortisone has been used, the support of the blood pressure both during and after operation has presented few problems In the early cases an intravenous drip of $\frac{N}{5}$ saline solution and 4% dextrose was maintained at both stages of the operation and during the immediate postoperative periods in case supporting fluid should be needed urgently, but in the later cases a drip has been set up only for the second stage Blood has been given when there was an associated anæmia Any fall in blood pressure during operation has been readily combated by a head down tilt, or very occasionally by intravenous methyl amphetamine ('Methedrine') A noradrenaline drip has never been required

As control of the blood pressure has been so successful, anæsthesia has presented few problems unless there was some associated disease A non explosive anæsthetic must be used in view of the need for diathermy and the proximity of the pleura *Because of the position required for operation,* controlled respiration has been found necessary both to provide a quiet operation field and to combat the reduction in tidal excursion The standard thiopentone induction, followed by endotracheal nitrous oxide and oxygen and supported by intravenous tubocurarine and pethidine has proved ideal for this purpose In positioning the patient, great care has to be taken to avoid pathological fracture of the ribs or vertebræ

Operative

The original two stage procedure through the flank has been persisted with because we decided not to modify our procedure while it was under investigation But it also has certain inherent advantages It is, on the whole, safer than the method of removing both adrenal glands at the same sitting, and it has the advantage, over the abdominal approach that enlargement of the liver by secondaries does not gravely impede the operation on the right side, and a good exposure is always possible, enabling accessory adrenal tissue in the vicinity to be found and removed

At the first stage the abdomen is explored and oöphorectomy performed This is done whether or not the ovaries have been allegedly destroyed by X rays or by previous surgery The patient is then turned on to the left side and, after removal of the twelfth or the eleventh rib, whichever is the more prominent, the right adrenal is removed through the flank 10 days later the left adrenal is removed by the corresponding route

Postoperative Management

For all practical purposes the postoperative regime after the first adrenalectomy is the same as after the second There is always the possibility that, at the first operation, the only functional adrenal gland has been removed, and therefore full cortisone cover may have to be provided. Table I gives the basic plan of administering cortisone, deoxycortone salt, and antibiotics throughout both operations Although the plan has been adhered to in most cases, it is only a general guide

We provide penicillin and streptomycin cover during both operations *This is necessary for three reasons* (1) owing to a low blood pressure the patient may have to be kept flat in bed for longer than usual thereby increasing the likelihood of chest infection, (2) many patients have chest secondaries and therefore have little respiratory reserve if they contract a slight infection, and (3) cortisone favours the development of infection in the chest or the wound

Morphine is not given as a postoperative analgesic, because the presence of secondaries in the liver would delay its breakdown Pethidine 50–100 mg is used instead

Except in the immediate postoperative period the nursing care is the same as that after any major operation Owing to

the poor general condition of many of these patients wounds tend to heal slowly. Accordingly, stitches are left in longer than usual, especially the continuous skin suture in the loin incision at the first stage. (This is left in during the second operation because of the risk of the wound's breaking down while the patient is being turned on the table.)

Postoperative Complications

The abdominal incision broke down in one case, on the 8th postoperative day. The first stage loin incision also broke down in a further case, on the 1st day after the second stage. Both healed well on further suture. There was one case of wound infection, which cleared under antibiotic therapy, and there were three cases of urinary infection. Two of these responded quickly to treatment, but in the third the infection persisted until the patient died, when it was found at necropsy to be due to growth in the bladder wall. There was one severe postoperative chest complication—a massive collapse of the left lung which precipitated the patient's death. Apart from this there were several minor chest complications, but these resolved quickly under treatment. There have been no cases of deep vein thrombosis and no pulmonary emboli.

Technique of Hypophysectomy

Preoperative

Patients are usually admitted to hospital 7–10 days before the operation. The first 2–4 days are occupied in assessing the stage of the disease and in obtaining such data as the urinary excretion of 17 ketosteroids and the uptake of radioactive iodine by the thyroid gland, as a base line for subsequent determination of residual pituitary function. For 6 days before the operation cortisone is given: at first the dosage is 50 mg daily by mouth, but during the last 2 or 3 days it is increased, reaching 400 mg (in divided doses) on the day of operation, half by mouth and half intramuscularly. During this long period of preoperative preparation the opportunity is also taken to aspirate massive pleural effusions or ascites so as to lessen dyspnœa and facilitate anæsthesia.

Operative

The operations are done under intratracheal anæsthesia (nitrous oxide, oxygen, and ether, or intravenous pethidine). A small right frontal craniotomy is performed with the patient in a slight reversed Trendelenburg position. This differs only in details from that described by Olivecrona (Luft and Olivecrona 1953) and by Bronson Ray (Pearson et al. 1956). The anterior limb of the bone flap is cut obliquely above the frontal air sinus so that its outer angle lies immediately above the external angular process of the frontal bone and so level with the floor of the anterior cranial fossa. From this direction (which makes an angle of 20–30° with the sagittal plane) the right frontal lobe is lifted off the anterior cranial fossa, and the chiasmal region is approached. Ready access to this region is always obtained by sucking cerebrospinal fluid (C.S.F.) from the cisterna chiasmaticus, and in no instance has preliminary drainage of C.S.F. either by the lumbar or the ventricular route, proved necessary. The two optic nerves and the chiasma are then uncovered by incising the arachnoidal wall of the cisterna chiasmaticus. Finally any remaining arachnoidal tissue in the concavity of the chiasma is divided, revealing the infundibulum (pituitary stalk) and the diaphragma sellæ.

The pituitary stalk is then clipped low down with a silver clip and divided below this, flush with the diaphragma. Next, the diaphragma is incised in a Y-shaped or X-shaped manner up to the line of the circular sinus, revealing the yellow pituitary gland. The gland itself is teased out of its fossa with a small dissector, sometimes in one piece but usually in fragments. Slight to moderate venous bleeding from the walls of the pituitary fossa often takes place during this stage but usually ceases after the bulk of the gland has been removed. The removal of the gland is completed by scraping the walls of its fossa with curettes and by inserting appropriately angled suction tubes. The most elusive portion of the gland is that tucked beneath the right optic nerve.

The pituitary fossa then appears as a small cavity lined by smooth red fibrous tissue. A pledget of cotton wool steeped in Zenker's fluid has been inserted into the fossa of all but 7 of the 30 patients for 2 or 3 minutes to necrose any tiny fragments of pituitary tissue which might have escaped removal. Precautions are taken during this manœuvre to prevent spilling of the fixative outside the pituitary fossa, and at its completion the walls of the fossa always appear grey. Finally, in all but two cases, before the craniotomy is closed, a plug of "cold curing" acrylic paste was placed in the pituitary fossa and allowed to set into a hard plate to prevent any possible regeneration of the pituitary stalk into the pituitary fossa.

Usually the operation progresses readily step by step, but in a few cases certain difficulties are encountered. In seven cases the chiasma was prefixed—i.e., less than 5 mm from the tuberculum sellæ—leaving little room for inserting the instruments. This difficulty, however, was overcome, as a rule, by chiselling away the hinder 3–4 mm of the tuberculum. In no case did section of the chiasma or of one optic nerve prove necessary for the exposure. In one case of prefixed chiasma however, the diaphragma sellæ was evidently tilted downwards and backwards away from the line of vision, the operation consequently was abandoned, and the case counted as a failure for hypophysectomy. In most cases a pint of blood was transfused during the operation, and in no case were hypotensive arterial techniques or hypothermia employed.

Postoperative

In general, the postoperative management causes no more concern than that after an operation for pituitary tumour. Recovery of consciousness is prompt, and the patient is usually drinking and eating again within a few hours.

Cortisone to a total of 350 mg is usually given on the day following operation, partly by mouth and partly intramuscularly; this is decreased in stages to an oral dose of 25 mg twice daily by the 8th day, at which level it is subsequently maintained. The scalp stitches are usually all removed by the 4th day, and, if the carcinomatous condition allows, the patient got out of bed between the 5th and 8th postoperative days.

Long-term Treatment

Patients who have been subjected to adrenalectomy or hypophysectomy are exposed to certain hazards for the rest of their lives. If these dangers are to be minimised, it is essential that maintenance therapy should be most carefully supervised, and that the closest coöperation should exist between the hospital and the general practitioner. It is our practice to see each patient as an outpatient at 4-week intervals, and doctors are asked to communicate with the hospital immediately if any untoward symptoms develop in any of these cases between visits.

At each attendance at hospital, the condition of any neoplastic lesion is assessed and the patient's weight and blood-pressure are recorded. Special inquiry is made about lassitude, anorexia, nausea, vomiting, or anything that might suggest infection.

In hypophysectomy cases the serum cholesterol level is estimated from time to time to assess thyroid function. Electrolyte studies have been carried out in all patients in whom there was reason to suspect incipient adrenal deficiency clinically. The importance of rising serum potassium and blood urea levels has been emphasised in this connection.

Though hypophysectomised patients require certain additional therapeutic measures (see below), the maintenance treatment of all the patients was made as similar as possible.

Cortisone

The standard dosage is 25 mg. twice daily by mouth. This probably represents an increase of about 50% above the glucocorticoid production of a normal person, but it provides an added safeguard against minor stress and infections; and, although a few patients developed some rounding of the face on this dosage, no serious side effects have been observed. Occasionally patients who are going downhill have been temporarily improved subjectively by raising the dosage of cortisone to 75 mg. or 100 mg. daily, but the necessity for such an increase has always been an ominous prognostic sign signifying that the carcinoma was progressing rapidly.

The importance of a very substantial increase in cortisone dosage at the time of an acute infection or accident is discussed below.

Deoxycortone Acetate

Though cortisone 50 mg. daily provides adequate replacement therapy for the adrenal glucocorticoids, its effect on the metabolism of salt and water is by no means always so satisfactory, with the result that, unless additional therapy is given, arterial hypotension, excessive depletion of sodium with hyperkalæmia, and a rise in the blood-urea level may occasionally develop. While this complication can usually be avoided by giving large quantities of sodium chloride, the administration of a mineralocorticoid seems to be a wise procedure, and all our patients received an implant of deoxycortone acetate 300 mg. before discharge from hospital. Thirteen patients (nine adrenalectomies, four hypophysectomies) were slightly hypertensive in the ensuing months on this routine, but the blood-pressure of most of these had been slightly raised before operation, and in only one case were any symptoms reported which could in any way be attributed to hypertension. Three patients (two adrenalectomies, one hypophysectomy) required reimplantation at 9, 9, and 16 months because their blood-pressure was tending to fall to hypotensive levels.

Sodium Chloride

Sodium chloride in the form of capsules is not given routinely to our patients save in the immediate period following adrenalectomy. We do, however, use it as a "fine adjustment" to keep the blood-pressure in the normotensive range. It is given as salt capsules in doses of up to 4 g. daily. Patients who tend to have a raised blood-pressure are forbidden table salt. Additional sodium chloride was very rarely required in the hypophysectomy cases.

Special Maintenance Therapy after Hypophysectomy

Phenobarbitone.—To minimise the possibility of epileptic fits all the patients received phenobarbitone 30 mg. twice daily for a year after hypophysectomy. After discharge from hospital no fits occurred except in one patient who was known to have cerebral metastases.

Control of diabetes insipidus.—Thirst and polyuria, often severe, usually developed within a week of hypophysectomy, but occasionally the onset was delayed a month or more. They were temporary and cleared spontaneously between the 4th and 11th months in all the survivors. In many patients sleep was seriously disturbed. Satisfactory control was usually obtained by the insufflation of posterior pituitary snuff 40 mg. from once to three times daily. One patient could tolerate only half this dose. In the early postoperative period injections of vasopressin tannate 5 mg. in oil were occasionally required each 2nd or 3rd day.

Thyroid.—Most patients showed a substantial gain in weight after hypophysectomy. Though this was partly due to an increase in appetite and general well-being, there can be no doubt that incipient thyroid deficiency often contributed to it. Some patients became frankly myxœdematous. These changes were not usually obvious until after the passage of several months, but in three cases they developed within a few weeks. In view of any possible effect it might exert on the carcinoma, it had been decided not to administer thyroid extract routinely; but in nine patients the onset of definite myxœdema made it essential. It was given by mouth in the dosage of 30 mg. twice daily, starting 2–18 months after the operation. The serum-cholesterol level, which in one case rose to 502 mg. per 100 ml., provided a simple satisfactory test for measuring the deficiency of thyroid during surveillance. The administration of thyroid did not appear to affect the neoplasm in any way, though the number of patients observed is too small for any statistical conclusions to be drawn. In fact, we feel that we were rather too hesitant in giving thyroid and consider that it should probably be administered to the majority of these patients after hypophysectomy.

Testosterone.—In view of the possible effect on the carcinoma, no patients in this series received testosterone at any time after these operations.

Management of Infections and Accidents

Although hypophysectomised or adrenalectomised patients can remain in good health on the maintenance therapy outlined above, the onset of an acute infection or the stress of an accident or an operation calls for a substantial increase in the adrenal steroids. As these patients cannot provide this from their own sources, fatal collapse may follow unless the cortisone dosage is increased. During any pyrexial illness, therefore, the daily amount of cortisone should be increased to about 150 mg.; and this must be combined with large doses of antibiotics. Vomiting is a danger sign of incipient adrenal collapse; but it is sometimes absent, and the blood-pressure may remain within normal limits until a few hours before death.

The dictum that, because it depresses the natural response to infection cortisone should be withheld at these times cannot be too strongly condemned. It is equally important to combat the stress of an operation or an accident by a similar increase in dosage, and any adverse effect upon tissue healing is unimportant.

Three of our patients died after fracture of the femur.

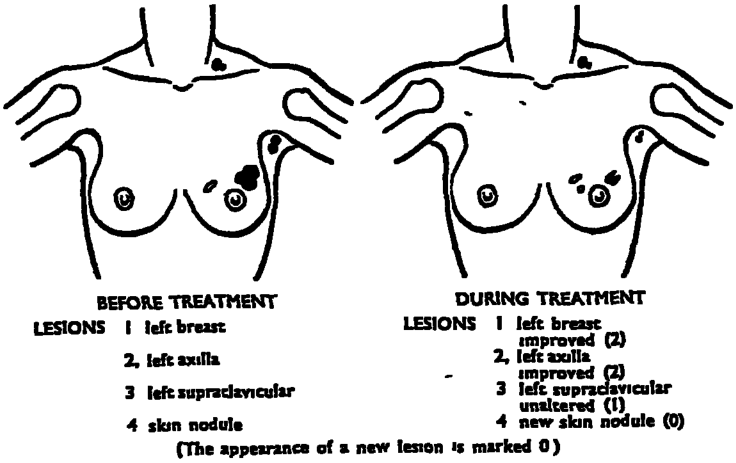
In two cases, both adrenalectomies, the fracture was pathological and a Thomas splint was applied. Unfortunately they were admitted as emergencies, and the cortisone was continued at the maintenance dose of 50 mg. daily. Both patients died within 3 days.

The third case, a hypophysectomy, was particularly tragic because the patient was doing extremely well and the fracture was in a healthy femur. She was admitted to a hospital where she was not known and remained well for 4 days on her maintenance dosage of cortisone. On the 4th day the femur was exposed and pinned under general anæsthesia, and she collapsed with arterial hypotension and died within 12 hours.

If such tragedies are to be avoided, it seems sensible to give all these patients a letter or card stating the necessity for increasing the dosage of cortisone at times of stress, so that they can hand it to any doctor who may be called to attend them if they are taken ill or injured away from the care of their own practitioners, and we intend to introduce this procedure.

Method of Assessment of Results

To assess the value of any treatment applied to cases of advanced cancer at the breast clinic, and particularly in comparing one method of treatment with another, it has been necessary to use the "mean clinical value" (M.C.V.) system introduced by Walpole and Paterson (1949) whereby a number between 0 and 12 is assigned to the patient at each 4-weekly visit according to her response to treatment.



BEFORE TREATMENT
LESIONS 1 left breast
2, left axilla
3 left supraclavicular
4 skin nodule
DURING TREATMENT
LESIONS 1 left breast improved (2)
2, left axilla improved (2)
3 left supraclavicular unaltered (1)
4 new skin nodule (0)
(The appearance of a new lesion is marked 0)

$$\text{M C V} = \frac{\text{Total marks}}{\text{No of lesions}} = \text{Average mark} \times 6 \text{ to produce a suitable number}$$

Maximum = 12
No effect = 6
Minimum = 0

$$\text{In present case M C V} = \frac{2+2+1+0}{4} \times 6 = 7.5$$

Fig 1—Assessment of mean clinical value

The system is applied by establishing a base-line for each demonstrable lesion when the patient is first seen and before treatment is begun Lumps are carefully measured, skin lesions photographed, radiographs of chest and skeletal lesions taken, and abnormalities measured and recorded With the exception of pain, subjective symptoms have not been used as factors in determining response The treatment is then applied and the patient seen again in 4 weeks' time Each lesion is again assessed. If the lesion has improved it is given 2 marks, if stationary, 1 mark, and if worse, 0 The marks are then added, and the total is divided by the number of lesions, giving an average mark for the whole disease Such a figure would be awkward to handle, so the result is multiplied by 6

In this way, if all the lesions are responding, the average mark is 2 and the M C V 12, if all the lesions are stationary, the average mark is 1 and the M C V 6, and, if all are deteriorating, the M C V is 0 When, as not infrequently happens, some lesions are responding and others are failing to respond or are deteriorating, any value intermediate between 0 and 12 may be obtained The working of the scheme is illustrated by a hypothetical case in fig 1

Each 4 weeks the patient is reassessed and a fresh M C V allotted, in this way a chart of the patient's progress can be made, and a typical chart following, for instance, œstrogen therapy is shown in fig 2 If one of the factors used in computing the M C V is radiological, a new radiograph is not taken every 4 weeks but at every third visit—i e, after 12 weeks have elapsed—and the previous value of the radiological factor is used to compute the M C V. in the two intervening assessments

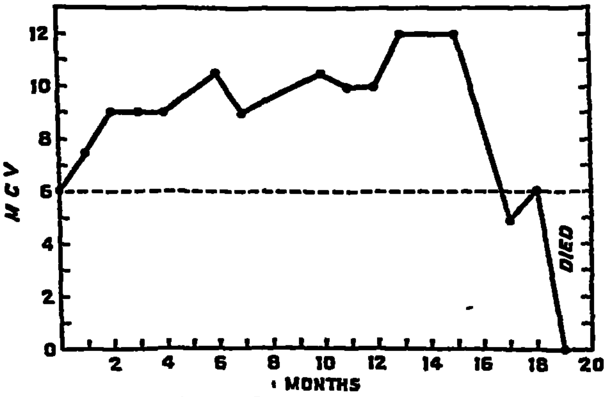


Fig 2—Typical chart of progress after œstrogen therapy

It must be understood that the state of any lesion is always compared with the *original* state of that lesion and not with its state at the previous visit Thus a patient who has been responding to treatment may cease to respond and begin to deteriorate, but the deterioration is not reflected in the M C V chart, because the lesions are still better than they were before treatment began This is a weakness of the method which cannot be avoided and it accounts for the somewhat precipitate drop in the chart shortly before death The workers at the breast clinic have, however, had many years' experience of this system and are convinced that it gives an accurate numerical assessment of the patient's response to treatment, particularly when comparative figures are required

In comparing the results of a series of patients treated by one method with a series treated by another it is possible to construct two charts One chart represents the average M C V of all the patients after 1 month, 2 months, 3 months, and so on, treated by one of the two methods The other does the same thing for the second method of treatment In this way the general effect of the two methods of treatment can be compared at a glance (fig 3) In constructing this chart, and to obtain the average in the later months, patients who have died maintain their representation on the chart with a mark of 0 Thus, when all the patients have died, both graphs reach zero

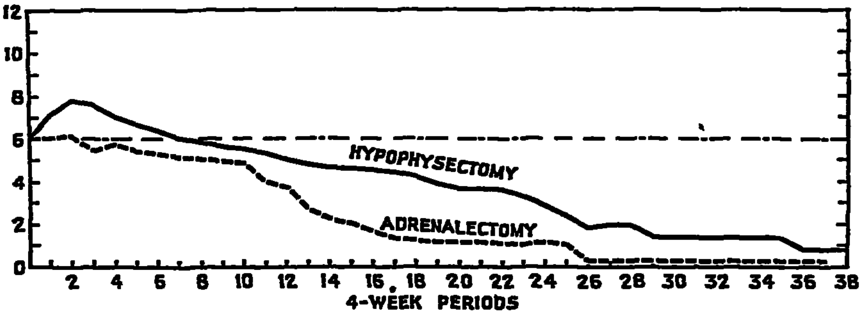

Fig 3—Average M C V (4-weekly records) of all adrenalectomy and hypophysectomy cases.

Results

Comparison of Groups

Although the thirty cases in each group were selected by random sampling, it was possible that, by chance, one group might have had a predominance of a particular type of case Tables II–V have therefore been compiled to compare the more important preoperative features of the cases falling into the two groups It can be seen that the incidence of these features in the two groups is about the same, indicating that they are comparable

The diagnosis was confirmed histologically in twenty-six of the thirty patients in each group In the eight cases not so confirmed the manifestations were so gross and characteristic that the diagnosis was not considered to be in any doubt

Mortality and Morbidity

Adrenalectomy—Of the thirty patients submitted to this operation twenty have now died One of these deaths, from massive pulmonary collapse 24 hours after

TABLE II—AGE IN YEARS

Operation	Youngest	Oldest	Average
Adrenalectomy	39	69	53
Hypophysectomy	36	73	54

the first stage adrenalectomy and oophorectomy, is held to be due to the operation If this case is included, four patients died within 1 month and nine within 3 months of operation In one case, where the ovaries could not be removed because of massive pelvic secondaries, the operation was technically impossible

There were few serious sequelæ as a direct result of the operation Two patients had addisonian crises some months after operation, but both responded well to treatment Two had depressive states during the first 2 months, one of these responded well to electroconvulsive therapy, but the other died from the carcinoma before psychiatry could be applied Two patients died after pathological fracture of the femur, these have already been mentioned and were deteriorating rapidly at the time of their accidents One patient developed an incisional hernia through the scar in one loin, but this was symptomless and needed no treatment

Hypophysectomy —Of the thirty patients submitted to this operation seventeen have now died No death was due to the operation Three patients died within 1 month and five within 3 months of operation, in none of these cases was death accelerated by surgery Two of the seventeen deaths were due to causes other than carcinoma of the breast one patient, aged 73, died of heart-failure 4 months after operation, and the other of arterial hypotension following open reduction of a fractured femur 6 months after operation, both were otherwise doing well One patient had a depressive state which recovered without treatment

TABLE III—MENSTRUAL HISTORY

Operation	Premenopausal	Menopausal	Postmenopausal	Unknown (hysterectomy)
Adrenalectomy	5	1	23	1
Hypophysectomy	3	3	21	3

The operation was technically impossible in one case owing to the abnormal configuration of the pituitary fossa This patient subsequently underwent adrenalectomy and is therefore included in both groups, the M C V for hypophysectomy being recorded as 0

Some degree of diabetes insipidus developed in all cases usually in the 1st week, but this complication was occasionally delayed until the 3rd week, and vasopressin, either as an injection of the tannate in oil in the acute stages or as snuff, was sometimes necessary The symptoms progressively declined and were usually insignificant by the 6th month

A bitemporal field defect was observed in six cases, but in only one did it cause trouble Most of the patients had unilateral anosmia, a few had bilateral anosmia, and none complained of it

Conclusions

The object of this investigation was to determine which operation (adrenalectomy or hypophysectomy) conferred greater benefit in cases of advanced cancer of the breast —without regard to the type of cancer or the patient's age We wanted a statistically valid answer rather than a *clinical impression*

Table VI shows that, of the patients who have already died, those who underwent hypophysectomy have survived on an average 2 months longer than those who underwent adrenalectomy If all the cases are included the patients who underwent hypophysectomy survived on an average 4 months longer than those who underwent adrenalectomy The longest survival after hypophysectomy was a year longer than the longest survival after adrenalectomy

TABLE IV—RESPONSE TO HORMONES

Operation	Poor	Fair	Good
Adrenalectomy	19	9	2
Hypophysectomy	22	6	2

The progressive mortality of the two groups is given in fig 4, which shows that during the period of follow up the mortality-rate after adrenalectomy climbed more steeply than that after hypophysectomy

By calculating the M C V we have compared the degree of benefit conferred When all the M C V in both groups are recorded on the same chart, the picture is too confusing for immediate analysis It may be simplified by taking an average of the M C V at each 4 weeks of all the patients treated by one method and constructing a single-line graph exemplifying an average response for that method A similar single line is constructed for the other method (fig 3) In this way the relative effects of the two methods can be readily appreciated

These findings (table VII) suggest that, in the circumstances of the investigation, if the ablation of endocrine tissue is indicated in a case of advanced cancer of the breast, hypophysectomy is to be preferred to adrenalectomy with oophorectomy We have been advised, however, by Dr P Armitage, who, with the kind cooperation of Prof A Bradford Hill, analysed our results, that this difference is not statistically significant in the conventionally accepted sense The degree of significance is indicated in table VIII

TABLE V—MANIFESTATIONS

Operation	Primary growth not removed	Secondaries in						
		Breast	Skin	Glands	Liver	Chest	Bone	[illegible]
Adrenalectomy	8	11	16	18	6	8	18	3
Hypophysectomy	6	5	14	14	5	11	16	3

Review of Reasons for Success or Failure

The fact that some cases respond while others do not may often depend on the nature of the growth—i e , whether or not it is what Huggins has termed "hormone-dependent" On the other hand, certain other factors may be important In the case of adrenalectomy, for instance, there may be accessory adrenal tissue which is at some distance from the operation site and is not removed at the operation, or other organs may take over the elaboration of œstrogen when the ovaries and adrenal glands have been removed Furthermore, after this operation the growth-promoting hormone of the pituitary gland is unaffected, and this hormone may be of importance in maintaining the cancer

TABLE VII—AVERAGE M C V

M C V	Hypophysectomy	Adrenalectomy
At 3 months	7 90	5 70
At 6 months	6 49	5 54
Last record	4 70	3 11
Average during survival	7 35	6 03

Likewise in the case of hypophysectomy the operation may not be complete Other workers have assessed the completeness of the operation on the basis of certain tests of pituitary function, but in our experience these tests are inconclusive Thus Luft and Olivecrona (1953, 1955) utilised the fall in the blood eosinophils with intramuscular injection of adrenaline, and the fall in the daily urinary excretion of 17-ketosteroids, as indicating how far pituitary function was destroyed We, however, found that, in our patients, the blood-eosinophil levels were constantly so low (less than 100 cells per c mm) that the response to adrenaline was valueless Again, probably because we gave rather larger doses of cortisone for maintenance therapy, the urinary excretion of 17-ketosteroids seldom decreased but stayed at 7–8 mg per day Ray and his collaborators (Pearson et al 1956) relied on tests of thyroid function they estimated the uptake of radioactive iodine and the amount of protein-bound iodine in the serum We also used these tests, in nineteen of our patients, and likewise found that the levels fell to low or very low values, indicating much diminution of thyroid function However, we were disappointed to find that this did not prove that the whole of the pituitary gland had been removed

TABLE VIII—STATISTICAL EVALUATION OF RESULTS

M C.V	Difference between means ± standard error
At 3 months	2 20 ±1 2 (t=1 73 , P=0 09)
At 6 months	0 95 ±1 44(t=0 66 P=0 51)
Last record	1 60 ±1 34(t=1 19 , P=0 24)
Average during survival	1 32 ±0 97(t=1 35 P=0 18)

Thus, in fatal cases which came to necropsy the pathologists usually reported that, to the naked eye, the pituitary fossa appeared empty However, on careful histological examination, Prof C W Harris and Dr J V Cavanagh have found microscopic fragments of glandular tissue in all six cases so far examined, and provisional estimates place the amount of residual glandular tissue as 1–10% of the anterior lobe In five of the cases so examined the patient had not responded to operation, but the sixth patient had benefited considerably and died after an operation for traumatic fracture of the femur 6 months after hypophysectomy while the carcinomatous lesions were still regressing Thus an absolutely complete hypophysectomy is not essential for producing regression

We must face the fact that, in some of our surviving patients, the hypophysectomy, although extensive, may still have been incomplete, and therefore we must consider other explanations of the benefit Several workers have shown that, in laboratory animals, if the pituitary stalk is cut through and an obturator is inserted to prevent reunion of the stalk with the gland, the gonadal, adrenal, and thyroid functions will be depressed in much the same way as after complete hypophysectomy (Harris 1955) In such circumstances the anterior lobe of the pituitary gland often shows histologically only slight necrosis The essential factor appears to be the interruption of the portal venous circulation of the pituitary gland , for if the stalk is allowed to reunite with the gland, the portal circulation regenerates and the animal regains its normal endocrine functions How far these experimental observations can be applied to man is not yet known

Dorothy Russell (1956) has reported that, in two patients operated on for craniopharyngioma, extensive necrosis of the pituitary gland followed section of its stalk without insertion of an obturator Neurosurgeons who have divided the pituitary stalk for breast carcinoma have subsequently found only a small proportion of the anterior lobe atrophic (Connolly 1956, Le Beau 1956)

A controlled trial of surgical hypophysectomy versus section of the pituitary stalk (with precautions to prevent its regeneration) therefore seems necessary to elucidate the rationale of our operation , for not only did we divide the pituitary stalk and attempt to remove the gland but also we inserted an acrylic plate to prevent regeneration of the portal circulation to any fragments which might remain

Comment

In this clinical experiment the differences between the results of hypophysectomy and those of adrenalectomy in the treatment of advanced carcinoma of the breast are not statistically significant Nevertheless there is a definite trend in favour of hypophysectomy , and it may well be that, with larger numbers of patients, significant differences will appear It must be realised, however that these results depend on a first class neurosurgical service, and today facilities are not yet available for all patients to be submitted to hypophysectomy

For this reason we are interested in alternative methods of destroying the pituitary gland, such as those practised in this country by Forrest and Peebles Brown (1955) We hope that, with the cooperation of the authorities of Liverpool University, it will be possible to utilise the techniques described above to compare the clinical course of a series of cases treated by surgical hypophysectomy with that of a series in which the hypophysis has been destroyed by proton bombardment with the synchrocyclotron

Further investigation into the relative merits of hypophysectomy and pituitary-stalk section is also planned

Summary

A controlled series of patients with advanced cancer of the breast were operated on—half by adrenalectomy with oophorectomy, and half by hypophysectomy

The type of operation was decided by random selection

The results of these operations were compared by the method of "mean clinical value" and by the survival-rate

In the circumstances of the investigation the overall results of hypophysectomy seem to be superior to those of adrenalectomy with oophorectomy, but the results are not statistically significant

Neither operation appears to hold out prospects of permanent cure Possible reasons for this are discussed

Our thanks are due to Dr P Armitage, of the department of medical statistics at the London School of Hygiene and Tropical Medicine, for analysing our results statistically, to the Editor of the *Leeds Medical Journal* for permission to reproduce figs 1 and 2, and to Miss J Thorne for her accurate and painstaking work in keeping the M C V records We thank Miss Sylvia Treadgold for her help in producing the diagrams We are also indebted to Prof G W Harris for his advice, to Dr J G Gibson and Dr J H Ray for the radio active iodine studies, to Dr R C Willcox for determining the protein bound iodine, and to Dr P J Helliwell for a note on the anæsthesia

This work is, in part, supported by a grant from the British Empire Cancer Campaign

GUY'S HOSPITAL, LONDON

In an accompanying paper Atkins et al (1957) have compared the results of adrenalectomy with those of hypophysectomy in the treatment of 60 cases of mammary carcinomatosis *From the outset of their investigation* it was clear that a preoperative criterion was needed to distinguish which patients were likely to benefit from either procedure The importance of having such a criterion is emphasised by their observations that only half of the cases showed any improvement from either operation

It seemed possible that the solution of this problem might be found in differences in the preoperative excretion of hormones by such patients For this reason it would be useful to have a complete picture of the urinary excretion of pituitary sex, and adrenocortical hormones When our work started, however, the methods available for estimating pituitary hormones and œstrogens were in various ways open to criticism and were not easily applied as a routine in the laboratory We therefore decided to study the excretion of the 17 ketosteroids, because these reflect to some extent the hormonal activity of the adrenal cortex and can easily be estimated

It soon became obvious that there was no significant difference in the preoperative excretion of total neutral 17-ketosteroids between patients who benefited from operation and those who did not We therefore turned our attention to the study of the 17-ketosteroid fractions obtained by chromatography of the total neutral fraction on alumina columns This paper gives a preliminary report on our findings

Patients Studied

The 60 cases described by Atkins et al have been the subject of our investigation, but, because of the time taken to complete each estimation, only 15 of them have so far been completely studied Of these 15, 7 underwent adrenalectomy and 8 hypophysectomy (table I) The youngest was aged 40, the oldest was 59, and all were postmenopausal except for 2 who were at the menopause and 1 who had had a previous hysterectomy All had had male hormones preoperatively, except 1 who had had stilbœstrol only, 4 had taken both male and female hormones The table shows the specific hormone taken immediately preoperatively and the interval between the last dose and the first collection of urine It also shows the sites of the secondaries and whether the primary growth was removed or not The longest surviving patient has been followed up for twenty-four months and the shortest surviving for seven months, 7 deaths are indicated by asterisks

Methods

On admission to the ward urine was collected for seventy-two hours from each patient Further seventy two hour collections were obtained after operation at intervals of a fortnight, a month, three months, and six months These collections were preserved with crystalline thymol and salicylic acid (Bisset et al 1948) We deal here only with the preoperative collections

Extracts from the seventy-two hour collections of urine were prepared according to the technique of Dingemanse et al (1952) Their method was then modified as follows

Aliquots of each extract containing 8–12 mg of total neutral 17 ketosteroids, dissolved in 10 ml of benzene, were adsorbed on columns containing 30 g of alumina equilibrated over 19 7–21 0 N sulphuric acid The chromatograms were developed with benzene, benzene *plus 0 1% ethyl alcohol*, benzene plus 0 5% ethyl alcohol, and benzene plus 2 0% ethyl alcohol The total *Zimmermann* reacting substances (Zimmermann 1935) in each fraction were then estimated by the method of Holtorff and Koch (1940)

This method permits the separation of 11 deoxy 17 ketosteroids from those with a carbonyl or hydroxyl function at the eleventh carbon atom The 11 deoxy 17 ketosteroids consist primarily of etiocholanolone, dehydro epiandrosterone, androsterone, and their derivatives These compounds are the metabolites of testosterone, Δ 4 androstene-3 17 dione and dehydroepiandrosterone, to a lesser extent they reflect the metabolism of certain of the adrenocortical C^{21} steroids having a hydroxyl group at the seventeenth carbon atom but lacking a carbonyl or hydroxyl function at the eleventh carbon atom They are eluted from the column in fractions 20–60 In fractions 65–85 are eluted 17 ketosteroids having a hydroxyl or carbonyl group at the eleventh carbon atom This group includes 11 hydroxyetiocholanolone, 11 hydroxyandrosterone, 11 ketoandrosterone, and 11 ketoetiocholanolone They are present in the urine as the metabolic end products of the metabolism of cortisone, hydrocortisone, and adrenosterone

TABLE I—CLINICAL DETAILS OF 15 PATIENTS WITH MAMMARY CARCINOMATOSIS

Case no	Age (yr)	Menopause	Preoperative treatment with hormones	Hormone taken before first collection of urine	Interval between last dose and first collection of urine	Primary growth removed	Secondaries in						
							Breast	Skin	Gland	Liver	Chest	Bone	C N S

* Died

The method has certain well-known limitations

(1) We did not use any preliminary separation into ketonic and non ketonic fractions with Girard's reagent T This has the effect of introducing an error into the colorimetric computation of our results owing to the presence of non ketonic chromogens in some fractions

(2) Peaks which are represented on the charts do not contain one steroid alone but probably contain one which is there in predominant quantity and, possibly, several others which may be eluted with the main one in very much smaller quantities—i e , the method, as we used it, does not permit the resolution of very closely related substances For these reasons we do not attach much quantitative significance to the concentration of steroid found in each individual peak

(3) The acid hydrolysis of steroid conjugates in urine, which is used in this method, dehydrates trace amounts of 11-hydroxylated-17 ketosteroids to their Δ 9 derivatives which are eluted in group I

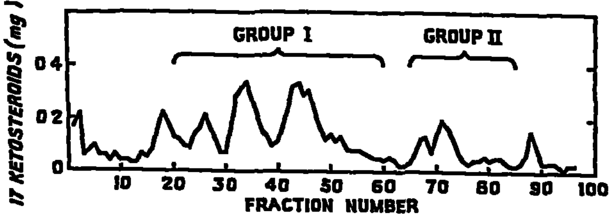

Fig 1—Excretion of 17-ketosteroid fractions in pooled urine from 20 healthy people

(4) In our hands the method has proved extremely time-consuming, and we do not consider it suitable in its present form for routine use

However, in view of the results we have obtained we consider it reasonable to compare the amount of steroids present in the first group (fractions 20–60) with the total amount of steroid material in the second group (fractions 65–85) Thus we have expressed as a ratio of the total amount of substances reacting with Zimmermann's reagent in group I to the total amount of substances giving the same reaction in group II

Results

The results can be shown graphically by plotting the quantity in each fraction against the fraction number When these plots are joined by a continuous line, it can be readily seen, by the peaks produced, in which fractions the 17-ketosteroids appear in greatest amounts

Fig 1 is the graph obtained for the 17 ketosteroids of pooled normal urines Breakdown of individual normal urines has shown that this is a representative picture If the total ketosteroids are worked out for the two groups in this figure, it is found that group I derivatives exceed group II in relative quantity by about 4 1 (4 1) This ratio naturally varies from one normal to another, but, if the quantity in group I is divided by that in group II, the result is usually about 3 or 4 and always more than 1

Fig 2 shows the graph obtained from the urine of a patient about to undergo hypophysectomy, and it can be seen that it is essentially normal in this respect The ratio of group I to group II is 3 7

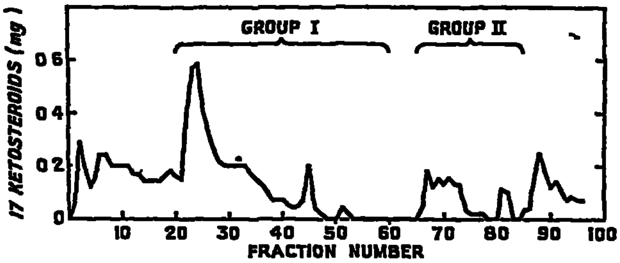

Fig 2—Preoperative excretion of 17 ketosteroid fractions in a patient who benefited from operation (case 7)

We have now investigated the preoperative urines of 15 patients and have calculated the ratio of group I group II in each case The result is shown in table II, together with the total 17-ketosteroids of these patients It can be seen that, although there is some variation from the normal, in 11 of the 15 cases the ratio is more than 1

In view of the 4 discrepant cases we tried to correlate the ratios of group I group II with clinical response to operation To do this we have used the " mean clinical value " (M C V) method of assessment (Walpole and Paterson 1949 , see also Atkins et al 1957)

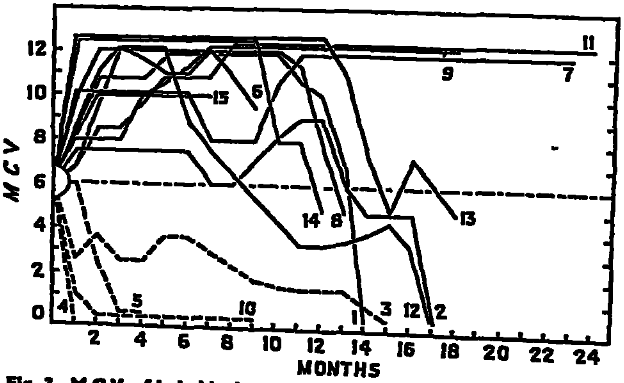

Fig 3—M C V of individual cases plotted on a single chart *continuous lines*, cases with ratio group I group II greater than 1 *interrupted lines*, cases with ratio less than 1

Fig 3 shows the result obtained when the M C V records for these 15 patients are plotted on a single chart It can be seen that, of these 15, 11 gave a fair to good response to either adrenalectomy or hypophysectomy, and that 4 showed no response at all and went straight downhill The graphs in fig 3 have been numbered to correspond with the case numbers in table II Comparison reveals that the 4 patients who did badly are those in whom the ratio was less than 1—i e , in these 4 patients the normal ratio of group-I group II 17-ketosteroids was reversed If all the M C V records of those patients with ratios greater than 1 are resolved to a single line, and the same done with those with ratios less than 1, the difference is more striking (fig 4) The charts of the fractional 17-ketosteroid excretion for these 4 patients are shown in detail in figs 5–8 It is, of course, impossible to say whether they had an excess of corticoid products in group II or less than normal androgenic products in group I

TABLE II—RATIO GROUP I TO GROUP II, AND TOTAL NEUTRAL 17-KETOSTEROIDS EXCRETED IN 72 HOURS

Case no	Ratio	Total 17 ketosteroids (mg per 72 hr)

14	1 2	10 9
15	3 0	23 7

Kellie (1955) found that, in a certain proportion of patients with neoplastic disease, there was a relative decrease in the excretion of 11-deoxy-17-ketosteroids and therefore a higher proportion of 17-ketosteroids with a carbonyl or hydroxyl group at C 11 Pincus et al (1955) found this to be a normal feature of ageing in healthy people The ages of the present 4 patients who showed a reversion of their excretion ratio of group-I (11-deoxy-17 ketosteroids) to group II (11 oxy 17-ketosteroids) were 47, 55, 55, and 53, hence it seems unlikely that ageing could have explained the finding We have no data on the ratio of group I group II in healthy women of these ages, but Pincus et al (1955) found that, even in women aged 70–79, the sum of the quantities of androsterone and etiocholanolone excreted in the urine exceeded that of the 11 oxygenated and 11 hydroxylated derivatives of these substances

Segaloff et al (1951) found that patients with mammary carcinomatosis who did not respond to treatment with testosterone propionate had an increased urinary excretion of glycogenic corticoids during treatment, whereas the patients who benefited from treatment had a decreased excretion of glycogenic corticoids They regarded this finding as of doubtful significance

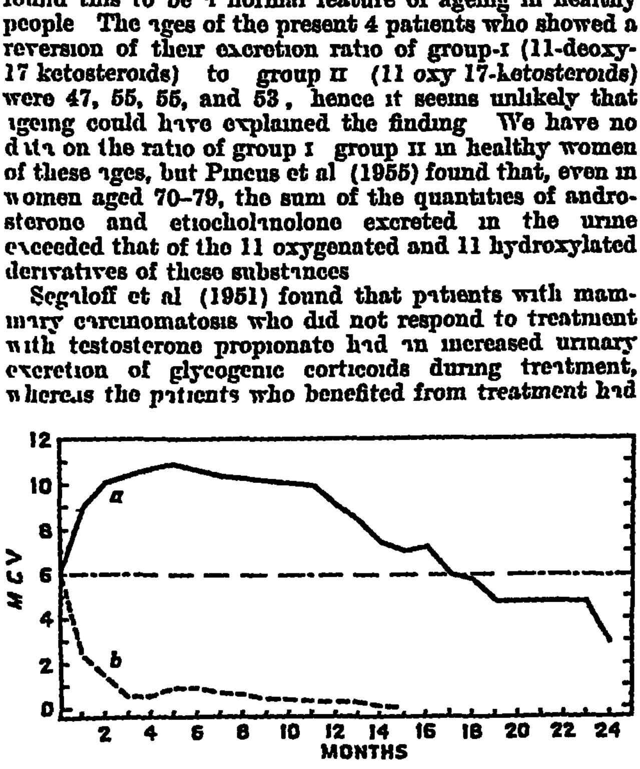

Fig 4—Resolution of M C.V into two lines a, ratio group I group II greater than I , b ratio less than I

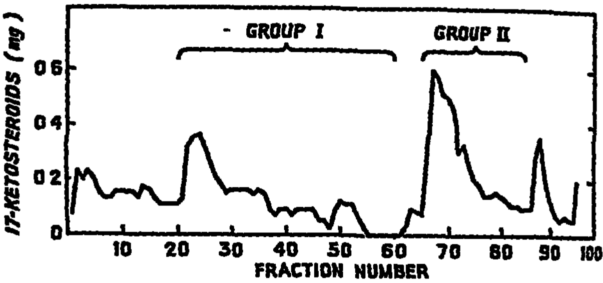

Fig 5—Case 3 preoperative excretion of 17 ketosteroid fractions (patient did not benefit from operation)

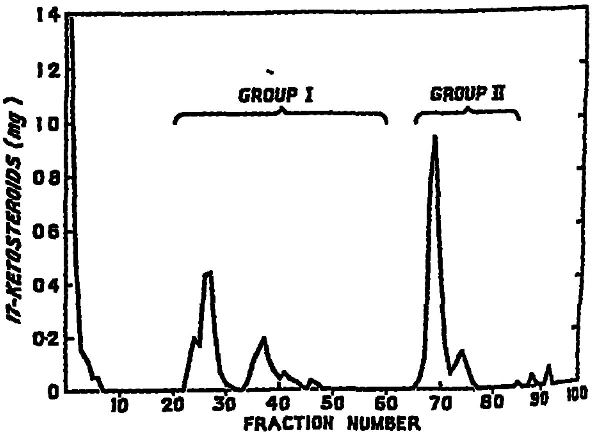

Fig 6—Case 4 : preoperative excretion of 17 ketosteroid fractions (patient did not benefit from operation)

Discussion

Treatment of advanced mammary carcinoma by altering the endocrine balance by various means is not new (Beatson 1896, De Courmelles 1922, Farrow and Woodard 1942, Haddow et al 1944) It was in 1941 that Huggins and Hodges described as "hormone dependent" those tumours of the prostate which responded to this type of treatment So long as treatment was by administration of sex hormones, the diagnosis of hormone dependency was a therapeutic one, but with the advent of major surgery (Huggins and Bergenstal 1952, Perrault 1952) it became desirable to foretell before operation which patients were likely to benefit Since then many attempts have been made to assess hormone dependency by various methods Emerson and Jessiman (1956) treated patients having bony metastases with provocative doses of stilbœstrol and measured the urinary calcium while the patients were on a constant dietary intake of calcium A rise in the urinary excretion of calcium indicated that the tumours were hormone dependent These workers further tested their patients by administering cortisone , and, if the urinary calcium fell and subjective symptomatic improvement occurred, they concluded again that the tumours were hormone dependent It seems to us that this method has the following disadvantages (1) it is only applicable to patients with bony metastases , and (2) the provocative doses of stilbœstrol may initiate a sudden deterioration in the patient's general condition which calls for immediate operation

We would like to have estimated the mammotrophic potency of our patients' urine (Hadfield 1956), but with the facilities at our disposal this was not possible

Huggins and Dao (1952) thought that the histological characteristics of the tumour might indicate the suscepti bility to endocrine treatment in certain cases, but this has not been the experience of one of us (J L H) in the present series Furthermore Wolff (1957) has failed to correlate preoperative mitotic cell counts with response to treatment

We do not suggest that our findings necessarily indicate hormone dependency in the tumours of the patients investigated, nor at this stage are we prepared to make any deductions from them about the relative proportions of the various adrenocortical steroids secreted (Dorfman 1954)

Not unexpectedly, in our studies of postoperative excretion of 17-ketosteroids, we found that in every case there was a complete reversal of excretion pattern compared with the normal steroids of group I were almost completely absent, whereas those of group II were much increased This presumably reflects the metabolism of the cortisone on which these patients were maintained a similar suggestion has been advanced by Strong et al (1956) An example is given in fig 9

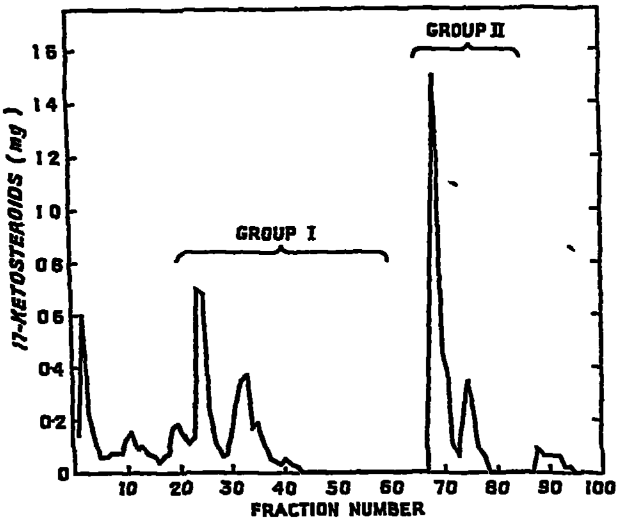

Fig 7—Case 5 preoperative excretion of 17-ketosteroid fractions (patient did not benefit from operation)

The similarity between this excretion pattern and that obtained preoperatively in the 4 patients in this series who did not respond to operation is striking From this it seems possible that the operation failed in these 4 cases because it did not alter decisively the internal hormonal environment, at least in as much as this is reflected in the results of fractional determination of 17-ketosteroids

The success or failure of an operation therefore may depend on its ability to produce a sudden change, with all its cellular metabolic consequences, in the hormonal environment of the tumour It is, however, common experience that operation merely defers the progress of the disease, and sooner or later all patients relapse It is therefore not impossible, in view of the similarity of the preoperative excretion of these 4 patients to that obtained after operation, that they had previously undergone a change in hormonal environment, from which they may or may not have benefited, and were at the time of coming to operation in the terminal stages of their disease.

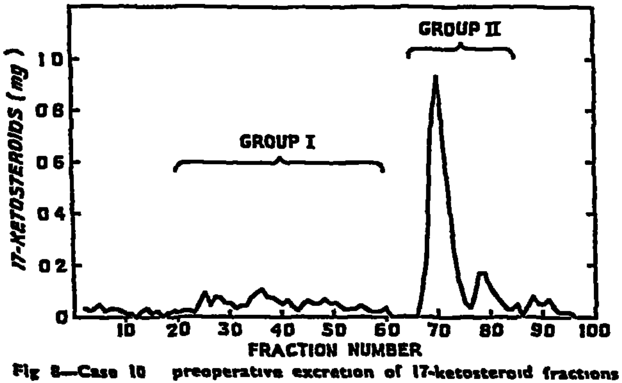

Fig 8—Case 10 preoperative excretion of 17-ketosteroid fractions (patient did not benefit from operation)

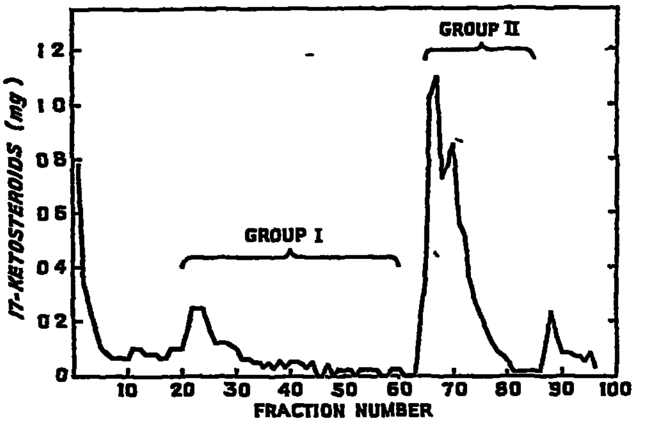

Fig 9—Excretion of 17 ketosteroid fractions a month after operation (patient maintained on cortisone 50 mg daily)

Summary

The excretion of the fractions of total neutral 17-ketosteroids in the urines of 15 patients with mammary carcinomatosis has been studied 11 patients benefited from either adrenalectomy or hypophysectomy, and 4 did not

The ratio of 11-deoxy-17-ketosteroids to 11-oxygenated or -hydroxylated-17-ketosteroids has been estimated in these patients

In those patients who benefited from operation the ratio was greater than 1 and the excretion pattern approximated to that found in healthy subjects In those who did not benefit the ratio was less than 1 and the excretion pattern closely resembled that found after operation

These results are discussed

We are grateful to Mr H J B Atkins, of the department of surgery, Guy's Hospital, Mr Murray Falconer, of the Guy's-Maudsley Neurosurgical Unit, and Dr K S MacLean, of the department of medicine, Guy's Hospital, for permission to study their patients, and Miss A M Norton for help with the technical work.

From the Virus Reference Laboratory, Colindale, London

BETWEEN September and December, 1955, material from patients in an outbreak of aseptic meningitis in East Suffolk (Garnett et al 1957) was received at the Virus Reference Laboratory, from Dr P H Martin of the Public Health Laboratory, Ipswich The material consisted of throat-washings, cerebrospinal fluid (C S F), fæces, and paired samples of serum

Virus Investigations

The C S F s, throat-washings (after centrifugation at low speed to remove gross debris), and bacteria free fæcal suspensions were inoculated into tissue culture tubes of HeLa cells and of monkey-kidney first-passage cells Three tubes of each cell type were used per specimen The inoculum consisted of 0 5 ml per tube of C S F , throat-washing, or 10% fæcal suspension, but in some instances 0 1 ml of a fivefold ultracentrifuge concentrate of fæcal suspension was used After preliminary incubation for one hour at 37°C the fluids were removed and replaced with fresh medium Cytopathogenic agents were readily isolated in monkey kidney but not in HeLa cells Details of the isolations are given in the accompanying table The newly isolated strains of virus were not neutralised by antiserum against the three types of poliomyelitis virus or against the Coxsackie viruses group A type 9 or group B types 1–5 inclusive

ISOLATIONS FROM EAST SUFFOLK MATERIAL

—	No	Last day post-onset, of a positive specimen	Virus isolated	No virus isolated
Patients	11		7	4
Fæces	11	10th	6	5
Gargles	10	3rd	4	6
C S F s	9	4th	5	4

Intraperitoneal inoculation into mice less than 24 hours old with first or second passage tissue culture-fluid suspensions of these strains resulted in varying degrees of paralysis amongst each litter, a proportion of the inoculated mice dying while others remained apparently unaffected Signs of infection in the mice were usually present four to five days after inoculation Histological examination of affected mice showed a generalised necrosis of varying severity in the skeletal muscles, the central nervous system and the visceral organs were unaffected The lesions suggested an infection by the Coxsackie A group of viruses

Serological Investigations

A number of sera showed in both neutralisation and complement fixation tests that there was no evidence of recent infection by the poliomyelitis viruses Tests by Dr P S Gardner for evidence of infection with the influenza A, B, and C viruses, the adenovirus group, mumps, psittacosis group viruses, lymphocytic chorio meningitis virus and *Rickettsia burneti* were negative, as were tests for leptospiral infection

All convalescent sera tested showed high neutralising antibody titres against one of the newly isolated strains of virus, and two patients had a greater than fourfold rise in neutralising antibody against their own strain of virus during the course of illness An antiserum prepared in a rhesus monkey against one of the strains of virus neutralised the homologous virus and also all the other strains isolated This antiserum subsequently has been found to neutralise virus strains isolated during 1956 from outbreaks of aseptic meningitis in Nottingham, Leicester, Sheffield, including the Haynes strain (Tyrrell and Snell 1956), Coventry, Hereford, South Middlesex, West Germany, and a strain obtained from Dr Rhodes, Hospital for Sick Children, Toronto, where it had been isolated from a child in the course of an outbreak of aseptic meningitis similar to that reported by Garnett et al (1957)

This antiserum also neutralised two strains of virus isolated at the Virus Reference Laboratory from the Bourn outbreak of aseptic meningitis (McLean and Melnick 1957), the prototype Hill strain of Echo virus type 9 received from Dr A B Sabin, and strains of virus isolated from babies during an outbreak of mild meningitis in East London in 1954 (Crawford et al 1956)

There have been two features of interest in the 1956 outbreaks from which these serologically related viruses were recovered (1) the presence of a rash noted in only a *proportion* of the patients who excreted virus; and (2) the effect of these viruses on newborn mice Even after one or two passages in tissue culture a number of strains failed to affect such mice, although others, including strains from the same outbreak, readily induced paralysis Further investigation of this phenomenon is in progress

Summary

Strains of virus, related to Echo virus type 9, have been recovered from cerebrospinal fluids, throat washings, and fæces of patients in a number of outbreaks of aseptic meningitis A proportion of these strains have been found to cause lesions of a Coxsackie group A character in newborn mice Rising or high titres of neutralising antibody against these viruses have been observed in the serum of patients, and tests with other possible ætiological agents have been negative

Acknowledgment is made to Dr J L Hamilton Paterson for histological reports, Dr A B Sabin and Dr D A J Tyrrell for strains of virus, Dr P H Martin and all those who submitted material for investigation, and Dr P S Gardner for the results of serological tests

The Leiston Outbreak

A SYNDROME suggestive of meningeal irritation was first observed by one of us (D G. G) in two adjacent villages a mile to the south of Leiston, at the beginning of September, 1955 These early cases occurred among young adults, predominantly male, and were the most severe of the outbreak They presented three essential symptoms (1) very intense and intractable headache,

(2) equally intractable vomiting, and (3) fever The illness was marked by short duration and an early return to work Soon cases began to appear among children and became more varied in symptomatology and duration, and, generally speaking, milder The disease, which was unlike any in our experience, appeared to be neither poliomyelitis nor cerebrospinal fever, although in some ways resembling both

New cases appeared every other day, and after a fortnight the infection spread into Leiston, mainly on a new housing-estate, so that by the end of the month we had seen 80 cases In October further cases appeared in various parts of the town, and there was a small spread to a village 3 miles to the north Dr P M Acheson, of Aldeburgh (4 miles to the south), informed us that he had experienced at the time, or shortly before, cases similar in type, while Dr A L Forster, of Yoxford (6 miles north of Leiston), had 1 severe case which was found to be a definite contact of one of our early cases, and which he had admitted to hospital Information was also received that an outbreak comparable in character had occurred in Lowestoft (25 miles to the north) in August (Hughes 1955, Eastwood 1956)

Finally, the local infection died out at the beginning of November, by which time we had seen upwards of 130 cases from 90 houses (2 or more cases in 25 houses) from a population of 5500 The cases involved all ages up to 50, with 40% appearing in the primary school age (5–11)

Symptoms were of varying intensity, and after an incubation period of two to four days consisted of any or all of

(1) Fever lasting up to four days, usually 100–101°, sometimes 103°, and in one patient 105°F (a boy of 6)

(2) Frontal headache, always described as across the forehead or behind the eyes

(3) Nausea and vomiting, frequent at the onset and incessant for two or three days in severe cases

(4) Pain of the neck and shoulders in more than half the patients, demonstrated by inability to flex the head to the knees This ceased when patients became afebrile

(5) Flushed face, suffused eyes, and photophobia

(6) Oral fœtor and a white tongue

(7) Rash in over 25% of cases (all except 3 in children) This usually appeared on the third day and consisted of blotchy reddish purple or pink macules on the face with or without a mixed rubelliform eruption on the neck, trunk, and extremities, which faded without staining in two or three days Numerous petechiæ on the trunk were present in 1 case

(8) Relapse occurred in 7 cases (3 of which were in children), up to six days after the onset, and was often worse than the initial attack

Recovery was complete in every instance, usually in two to five days, without paralysis, lymphadenopathy, or other residual effect

On the advice and with the cooperation of Dr P H Martin, of the Ipswich Public Health Laboratory, serum, garglings, and fæces were sent to the Virus Reference Laboratory, Colindale, in the following two cases

A girl of 15 was the 2nd case in a family of 11 In this family 7 children were involved over a period of nine days She had a flushed face with fever, vomiting, and backache, and recovered in four days The specimens were taken on the second day and blood was also taken after ten days and three months

A woman of 24 had fever (101°F) and frontal headache for two days and on the third day felt better and went out shopping The following day her son, aged 6 years, was feverish with headache and backache That evening she had a return of headache and fever which was worse the next day when the specimens were taken Blood was also taken after ten days and three months

AGE-DISTRIBUTION OF CASES

Age group (yr)	0–4	5–11	12–18	19–29	30–39	40–49	51	Total
Male	10	30	12	8	9	4		73
Female	13	23	5	11	4	2	1	59

Cases Admitted to Hospital

Some of the most severe cases of this illness in the region were admitted to hospital in Ipswich At first these came from the Leiston area As the epidemic spread there were further cases from the areas between Leiston and Ipswich, and finally a small series of cases came from Bramford to the north-west of Ipswich

Of the 15 hospital cases 14 were admitted because of signs of meningeal irritation, the other patient developed a pneumonia following a particularly severe bout of vomiting

While the patients were in hospital the distinction from non-paralytic poliomyelitis and other virus meningitis was not always clear In comparison with equivalent cases of poliomyelitis, these patients complained of more severe headache, and considerably more vomiting, and they all had a characteristic white furred tongue Only 3 patients developed rashes while in hospital The rash appeared on the face and upper trunk, rather bluish red with ill-defined margins, macular, but in irregular "blotchy" patterns The rash lasted one or two days

A lumbar puncture was performed on 11 of the patients The abnormalities in the cerebrospinal fluid (C S F) varied slightly, depending on the day of illness The C S F s obtained early in the illness showed high cell-counts of the order of 200–1000 cells per c mm with polymorphs predominating, but fluids collected later in the illness, as in other types of virus meningitis, showed a considerable predominance of lymphocytes On the whole, cell counts were higher than one would expect to find in cases of non paralytic poliomyelitis of similar severity The total protein in the 11 cases was never found to exceed 60 mg per 100 ml, and in 6 out of the 11 it did not exceed 30 mg per 100 ml Headache and vomiting were considerably relieved by lumbar puncture All patients made a complete recovery without any specific treatment White cell counts were within normal limits and Paul-Bunnell tests were negative Specimens of fæces from 9, gargle from 8, C S F from 9, and sera only from 7 were sent to the Virus Reference Laboratory from 15 of these cases, and from a similar case that was admitted to the local general hospital

Strains of virus were isolated from the girl of 15 described above and from 7 of the hospital patients and, as described by Boissard et al (1957), they were all immunologically similar and were related to the Echo-9 type of enteric virus (Committee on Echo Viruses 1955)

Summary

An illness occurred in Suffolk in September, 1955, which we had not seen before The predominant signs and symptoms were fever, headache, nausea and vomiting, pain in neck and shoulders, flushed face, photophobia, and, in about 25% of the cases (mostly children), a macular rash, often rubelliform in type Recovery was usually rapid and always complete, without paralysis or other residual effects

A large number of cells were present in the spinal fluid of the patients admitted to hospital, these were predominantly polymorphonuclear leucocytes in the early stage, and lymphocytes later

Strains of virus immunologically related to the Echo-9 type of enteric virus were isolated from the cerebrospinal fluid of 5 patients, from the stools of 6, and from throat washings of 4

Dr. Robert Fells Library
S. M. S. Medical College

We wish to thank Dr J W Paulley for permission to include details of the case admitted under his care, Dr R Wilton and Dr I Staddon who sent some of these cases into hospital for investigation and subsequently collected further specimens for investigation, and Dr P H Martin, Public Health Laboratory, Ipswich, for laboratory examination of the cerebrospinal fluids

MENINGITIS OF VIRUS ORIGIN

CHAVA EVE ROTEM
M D Lausanne
MEDICAL REGISTRAR,
LEICESTER ISOLATION HOSPITAL AND CHEST UNIT

IN July, 1956, the first examples of what appeared to be a new type of aseptic meningitis were admitted to the Leicester Isolation Hospital and Chest Unit This disease, apparently widespread all over England, was most prevalent in the Midlands Descriptions of a similar illness appeared under such titles as Trent valley fever, Nottingham meningitis (*Lancet* 1956), lymphocytic meningo encephalitis (Lyle 1956a), and seasonal aseptic meningitis (Karzon et al 1956) This paper gives a brief description of findings in the first 100 cases admitted to the Leicester Isolation Hospital between July 4 and Nov 23, 1956

Incidence

It is impossible to assess the number of cases in the population at large, because the disease is not notifiable and many cases were not admitted to hospital Of the 100 patients admitted to hospital, 58 were male and 42 female The age distribution is shown in table I, and the way in which the cases were divided between city and county, month by month, is set out in table II 4 cases involving hospital staff are included in the survey It will be noted that at the beginning of the epidemic there were more admissions from Leicester city than from the county

There was striking familial aggregation, as illustrated in table III

Usually, 1 or 2 members only of any one household were sent to hospital by the general practitioner, who, upon confirmation of the diagnosis, treated other members at home Some contacts had a mild illness only

Clinical Features

Dates of onset ran continuously, suggesting dissemination by contact rather than a common source Cases in any one household occurred at intervals of six to ten days

The onset was acute in 90 cases, and the hour of onset could often be obtained—e g, two lorry drivers were taken ill at the wheel, a policeman fainted on the beat and some school-children were taken ill in class 10 patients, however, gave a one to two weeks' history of insidious onset

TABLE I—AGE DISTRIBUTION

Age (years)					
1–5	6–10	11–20	21–30	31–40	41–55
13	31	14	23	14	5

TABLE II—MONTHLY DISTRIBUTION BETWEEN CITY AND COUNTY

—	July	August	Sept	Oct	Nov
City	14	18	8	10	3
County	7	3	9	23	5
Total	21	21	17	33	8

TABLE III—NUMBER OF CASES IN FAMILY

Number of cases per family	Number of families
1	71
2*	13
3*	8
4*	2
5*	1
Total	95

* Including some unconfirmed cases

Clinically the disease resembled the major illness of poliomyelitis without paralysis The presenting symptom was usually severe headache, as I had occasion to experience In children this was often preceded by vomiting Table IV gives further details There were no hallucinations, disorientation, unconsciousness, or abnormal neurological signs in any of the patients Pyrexia varied between 99°F and 105°F (average 102°F), lasting three to five days and subsiding by lysis in 90 cases

Illustrative Cases

(1) A man of 41 Admitted to hospital on Oct 11 On waking up on Oct 10 had rigors, frontal headache, which became worse, and frequent vomiting When neck rigidity developed he was transferred to hospital On Oct 10 his younger daughter had similar symptoms, was treated as flu, and improved after four days On admission 102·5°F pulse 84, respiration 26, alert and cooperative, no abnormality on physical examination except some neck rigidity Lumbar puncture 190 cells per c mm (78% lymphocytes), protein 60, chlorides 620, sugar 68 mg per 100 ml Blood Hb 96%, white cells 5300 per c mm (polymorphs 76%, lymphocytes 20%, monocytes 4%) Urine normal Afebrile after five days When seen on Nov 29 he was well, no further headaches and back to work for three weeks

TABLE IV—SYMPTOMS AND SIGNS

Symptom	No of cases
Pyrexia	100
Headache	100
Frontal and retro orbital	46
Others	54
Neck rigidity	96
Back stiffness	83
Vomiting	88
Maculopapular rash	16
Rigors	19
Photophobia	15
Drowsiness	8
Abdominal pains	8
Sore throat	4
Enlarged lymph glands	3
Constipation	Common

(2) A girl of 12 another daughter of previous patient Admitted on Oct 19 with twenty-four hours' history of headache, pyrexia, and vomiting Headache was bitemporal On admission 101°F, pulse 112 No abnormality on physical examination, except some neck rigidity Lumbar puncture 48 cells per c mm (85% lymphocytes), biochemistry normal Blood Hb 82%, white cells 6000 per c mm (polymorphs 73%, lymphocytes 27%) Urine normal Symptom free and afebrile from the sixth day onwards When seen on Dec 6 perfectly well

On Oct 25 her mother felt vaguely ill and sick and had a headache All this subsided after 2 days

In this family of 4 people, 2 had the typical condition and 2 must be assumed to have had a mild form only The intervals of onset were five days, eight days, and seven days respectively

Laboratory Findings

Routine diagnostic procedure in all cases included one or more lumbar punctures, full blood-count and film, and examination of urine Throat swabs were taken for culture, and specimens of cerebrospinal fluid (C S F)

TABLE V—HÆMATOLOGICAL FINDINGS

—	Findings	No of cases
Hb	Normal	100
White cells	Normal to slightly raised	77
	2900–4500	31
	10 000–13,000*	2
Average white count	5500	100
Neutrophils	70 % or more	100

* Superinfection with streptococci present if these 2 cases are excluded the average white count is 5380

fæces, blood, and throat washings were taken for complete virological studies

The blood findings are summarised in table V No toxic changes and no abnormal cells were seen in blood films

A Paul-Bunnell test in a number of cases was negative Throat swabs did not yield pathogenic organisms on culture, except for β hæmolytic streptococci (2), *Staphylococcus aureus* (1), *Streptococcus pneumoniæ* (1), and *Hæmophilus influenzæ* (1) Urine was normal in all cases

C S F pressure was often slightly raised and lumbar puncture sometimes improved headache No readings were taken from children The findings are given in tables VI and VII 3 patients with an initial C S F cell count exceeding 1000 per c mm showed a marked reduction in cell count three to four days later and in 3 others the initially only slightly raised count trebled C S F chlorides and sugar were within normal limits in all cases Bacteriological cultures of C S F were sterile

TABLE VI—ABNORMAL CEREBROSPINAL FLUIDS

—	No of cases	
Abnormal on admission	73	
Normal on admission	27	
Changes three to four days after admission		6
No change at second lumbar puncture		6
No second lumbar puncture performed		15
Total	100	27

Virological Studies

Throat washings, C.S.F., and fæces from all patients were cultured for virus Blood was taken in the acute and in the convalescent phase for serological tests Unfortunately, a second specimen of blood was not obtained from all patients

Virological studies on the first 30 cases were done at the Virus Reference Laboratory, Colindale, London From 22 of these cases a cytopathogenic agent was isolated in 19 cases from fæces, in 15 cases from C S F, and in 16 instances also from throat washings Furthermore in 1 case adenovirus (A P C group) was isolated, and in 1 case polio virus type I

A positive neutralisation test was obtained with the sera of 22 patients, using the virus isolated from one of them These viruses are similar to but not identical with Echo-9 virus (Boissard et al 1957) This virus belongs to a group recently isolated from the human intestinal tract during aseptic meningitis It has been proved distinct from poliomyelitis and Coxsackie virus (University of Buffalo 1956)

TABLE VII—CHANGES IN CEREBROSPINAL FLUID

—	No of cases	
Normal cell count	21	
Raised cell count	79	
5–100 cells per c mm		33
101–500		35
501–1000		6
1001–2593		5
		79
Lymphocytes below 35 %		3
Lymphocytes 50–100 %		76
		79
Proteins normal	59	
Raised proteins (all cases associated with pleocytosis)	41	
36–50 mg per 100 ml		20
51–100 mg		13*
101–150 mg		8
Average 66 3 mg (normal 10–35)		41

* In 1 patient proteins rose to 200 mg per 100 ml five days after admission

Complement fixation tests were negative for influenza A and B, psittacosis, lymphogranuloma venereum, Q fever, atypical pneumoniæ, lymphocytic choriomeningitis, and mumps, and positive in 1 case with normal C S F for adenovirus (A P C group)

Differential Diagnosis and Treatment

Differential diagnosis from non-paralytic poliomyelitis was difficult at the onset of the epidemic The virus meningitis is the less severe illness, with nuchal and spinal muscle spasm of shorter duration and more rapid recovery Familial aggregation is frequent, as opposed to its rarity in poliomyelitis Several cases sent to hospital as non-paralytic poliomyelitis were found to be meningitis of virus origin Some cases sent to hospital as virus meningitis proved to have a different condition—tonsillitis with meningism (5), meningococcal meningitis (1), cerebral abscess (1), neurosyphilis (2), tuberculous meningitis (2), paralytic poliomyelitis (3), cerebral thrombosis (1), and subarachnoid hæmorrhage (2) These points emphasise the importance of establishing the diagnosis by lumbar puncture in all cases presenting as meningitis

Apart from 2 patients initially suspected of having meningococcal meningitis who had a short course of penicillin, no specific treatment was given The common analgesics proved ineffective and had to be supplemented by pethidine Patients were kept in bed for seven to ten days and were advised upon discharge to rest for a further week

There was no mortality 89 patients were well when seen as outpatients six weeks after discharge, but most of them admitted to intermittent headache (especially after exertion) Recovery was slow and tiredness and mild depression were common There was no residual paresis, ataxia, or headache in children 10 patients complained spontaneously of frequent headache, and 1 patient had to be readmitted to hospital eight weeks after discharge for lumbar puncture, which proved normal

Discussion

The disease described here, which we call meningitis of virus origin (M V O), presents some distinctive clinical and pathological findings acute onset, pyrexia, and headache in all cases, signs of meningeal irritation and vomiting in most cases, rubelliform rash over face and upper extremities, sparing the trunk, and photophobia in some cases Incidence was highest in children and young adults On clinical evidence the present series appears homogenous, in spite of variations in C S F findings, in view of the incomplete virological studies, however, there is as yet no certainty of a common ætiological factor From 22 cases a virus akin to Echo virus type 9 was isolated, and from 1 case polio virus type I, but from 1 patient with normal C S F, adenovirus (A P C group) was isolated We do not know whether the normal C S F in this case was coincidental

The first isolated instances of an aseptic meningitis similar to the one described here were noted in 1955, and recently accounts appeared under various names in Britain and America The cases described in this paper differ from those described earlier—e g, in Nottingham meningitis (*Lancet* 1956), vertigo, and nystagmus were reported to be frequent and vomiting rare There were no rash and no prostration, and the maximum C S F cell count was 20 lymphocytes per c mm Dodd's (1956) clinical and laboratory findings, however, vary from ours in detail only Hesling (1956), on the other hand, reported severe lymphocytic leucocytosis, and an erythemato papular rash, mainly over trunk and face, in his 2 cases

The 125 cases of lymphocytic meningo encephalitis reported by Lyle (1956b) were similar to our cases, in particular in C S F findings 48 of his patients, however, had acute and severe myalagia, and though only 24 had much neck stiffness, 68 had neurological abnormalities not encountered in our series Some of Lyle's cases also had hepatitis or abnormal liver function tests The disease as seen by us did *not* usually conform to McAlpine's (1947) criteria of encephalitis (nystagmus, photophobia, and neck stiffness after fever and headache), as did the cases described by Lyle

Our series bears most resemblance to 24 cases described by Karzon et al (1956) in the U S A, which was called "seasonal aseptic meningitis" The causal agent isolated from Karzon's patients was Echo virus strain 6 Onset in July, household aggregation, and age incidence were all similar to those observed here The preponderance of males and the short duration of the epidemic described by Karzon might be accounted for by the localised outbreak in a closed community

There is little similarity between the condition described here and the outbreak at the Royal Free Hospital in 1955

Summary and Conclusions

100 patients suffering from an aseptic meningitis were admitted to the Leicester Isolation Hospital between July 4 and Nov 23, 1956 The main clinical features of the disease were acute onset, headache, pyrexia, vomiting, neck and back rigidity, and occasionally a rubelliform rash and photophobia A predominantly lymphocytic pleocytosis was found in the C S F of most patients Adenopathy was not a feature of the disease All patients recovered without specific treatment, and with no serious sequelæ A cytopathogenic virus related to Echo virus type 9 was isolated from fæces, C S F, and throat swabs in several cases It is concluded that this essentially benign disease is probably not identical with Lyle's lymphocytic meningo-encephalitis, but shows clinical similarity with cases described by Karzon and by Dodd

ADDENDUM

Since the present survey was concluded, more cases of N V O, some of increased severity, have been admitted to this hospital Monthly incidence is on the decline

I wish to thank Dr J C H Mackenzie, consultant and physician superintendent, for permission to publish this paper and for his helpful criticism, Dr N S Mair and Dr H J Mair for help and advice on virology and Dr J P Anderson and Dr J R Barton for the use of some of their case notes

THE mechanism whereby certain sulphonamides exert a hypoglycæmic and (in certain diabetics) an anti diabetic effect remains a matter of debate

The following explanations have been suggested inhibition *or destruction of glucagon secreting α cells* (Franke and Fuchs 1955, Mellinghoff 1955, Von Holt et al 1955, Ferner and Runge 1956), insulin sparing action (Kinsell *et al* 1956, Mohnicke 1956), inhibition of insulinase (Mirsky 1956, Mirsky et al 1956), increased production of insulin (Gepts et al 1955, 1956, Loubatières 1955, Ashworth and Haist 1956), *depression of gluconeogenesis by a direct effect on the* pituitary gland and the adrenal cortex, and increased permeability of the cells to glucose, possibly due to release of an inhibitor of hexokinase (Best 1956)

Although none of these hypotheses has been proved, in-vitro experiments have shown that hypoglycæmic drugs reduce the activity of certain enzyme systems in the liver (Clarke et al 1956, Hawkins et al 1956, Mohnicke and Knitsch 1956)

Many diabetics have already been treated with oral sulphonamide, but the results show that sulphonamide is no substitute for insulin and is only effective in "those subjects who possess a source of appreciable amounts of endogenous insulin" (*Wrenshall and Best 1956*)

Only a few clinical studies concerned with metabolic investigations have been published We report here *such studies made on diabetics treated with carbutamide* ('B Z 55')

Material

18 patients were kept in hospital for a few weeks on a 1500-calorie diet (carbohydrates 180 g, fats 50 g, and proteins 60 g) Afterwards they were under ambulatory control with a slightly more liberal diet Gross over weight was reduced before the start of treatment During the treatment the patients maintained their weight After 1–3 months' treatment the patients were readmitted for control metabolic studies

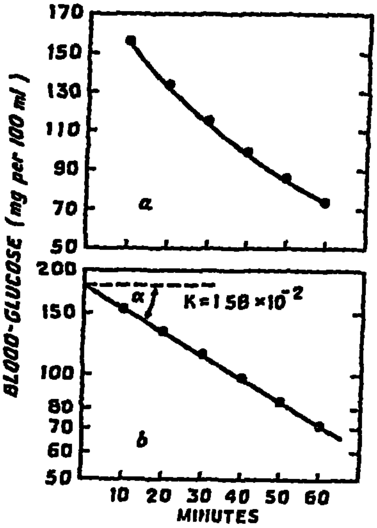

Fig 1—Intravenous glucose-tolerance curve in healthy people *a*, mean of observed values *b*, semilogarithmic line derived from *a*

16 of these patients, aged 42–82 had diabetes of the middle age onset type, they had or

had had some obesity but never acidosis, and their diabetes never needed much insulin treatment

Of the other 2 patients case 16 had had diabetes for twenty years, and occasionally ketosis had needed high-dosage insulin therapy, and case 18, aged 26, had mild recently discovered diabetes together with signs of adrenocortical hyperactivity (hirsuties, decreased menstruation, and increased urinary excretion of 17-ketosteroids)

Treatment

After an initial period of observation uniform treatment was given with carbutamide 4 g on the first day, 2 g on the second, and 1 g daily thereafter Occasionally, during protracted treatment, the dosage was reduced to 0·5 g daily

Methods

Glycosuria and glycæmia were frequently tested for by the Somogyi/Schaffer-Hartmann technique

Before any treatment, between the 6th and the 10th days of treatment and after 1, 2, or 3 months the following studies were made

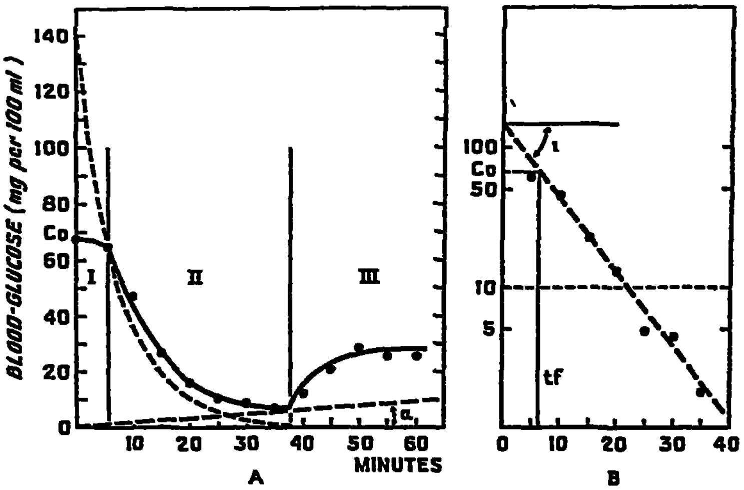

Fig 3—A, hypoglycæmic curve in healthy person after intravenous injection of insulin 0·1 u per kg of body-weight, I, first period, probably corresponding to fixation of insulin in tissues (tf), II, second period, corresponding to progressive lowering of blood-glucose level (Co) (exponential curve), III, third period, characterised by secondary rebound II corresponds either to exponential formula without residue or (as here) to exponential formula, with residue (a) Mathematical analysis yields this factor a corresponding to persisting output of glucose by liver (Franckson 1957)

B, after deduction of a logarithmic values of hypoglycæmic curve fall on straight line whose slope is indicated by t

(1) *Intravenous-glucose-tolerance Test*—It has been shown in this laboratory that, 10–60 minutes after a rapid intravenous infusion of glucose 0·33 g per kg of body-weight in a 50% solution, the rate of clearance of glucose from the blood is related to its uptake by the tissues Mathematical analysis of the blood glucose curve yields a glucose assimilation coefficient (Conard et al. 1953) (fig 1) In healthy people this factor is related to age and nutrition but is constant for any given person Its value ranges from 1·1 to 2·8, the mean figure calculated in 73 people being 1·8 ± 0·3 In diabetes it lies between 0·1 and 0·9 mean value 0·5 ± 0·2 (Conard 1955) (fig 2)

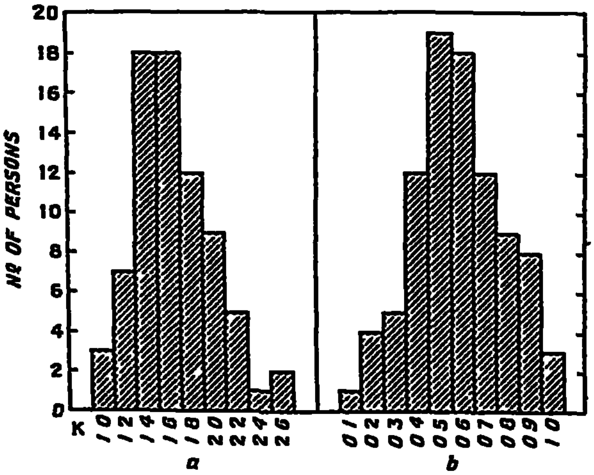

Fig 2—Distribution curve of glucose-assimilation coefficient (K) a, in 75 healthy people b, in 92 diabetics (Conard 1955)

(2) *Combined Intravenous Glucose and Insulin Test*—In this test, the same procedure is used with crystalline insulin 0·1 u per kg of body-weight added to the intravenous glucose The increase in the glucose assimilation coefficient is directly related to the activity of the injected insulin (Conard 1955)

(3) *Intravenous Insulin Test*—The intravenous injection of crystalline insulin 0·1 u per kg of body-weight induces a hypoglycæmic curve which, between the 5th and the 30th minutes after the injection, follows an exponential law From these curves Franckson (1957) calculated two factors one (i) corresponds to the actual hypoglycæmic effect of the hormone, the other (a) expresses the output of glucose by the liver (fig 3) In healthy people factor a is very small (0·0–0·5), indicating that, during insulin induced hypoglycæmia, the liver's output of sugar is very small

(4) *Blood-cholesterol and Total Lipids*—These were estimated in some of the patients—by the method of Schoenheimer and Sperry for cholesterol and Bloor's method for the total amount of fat in the blood

(5) *Plasma proteins* were estimated by Van Slyke's method and separated by electrophoresis on Whatman paper no 1.

Results

In all the cases the diabetic condition definitely improved, judged by the decrease of glycosuria, the fasting blood-sugar level, and the maintenance of body-weight For 18 cases the mean fasting blood-glucose level was 178 mg per 100 ml before treatment and

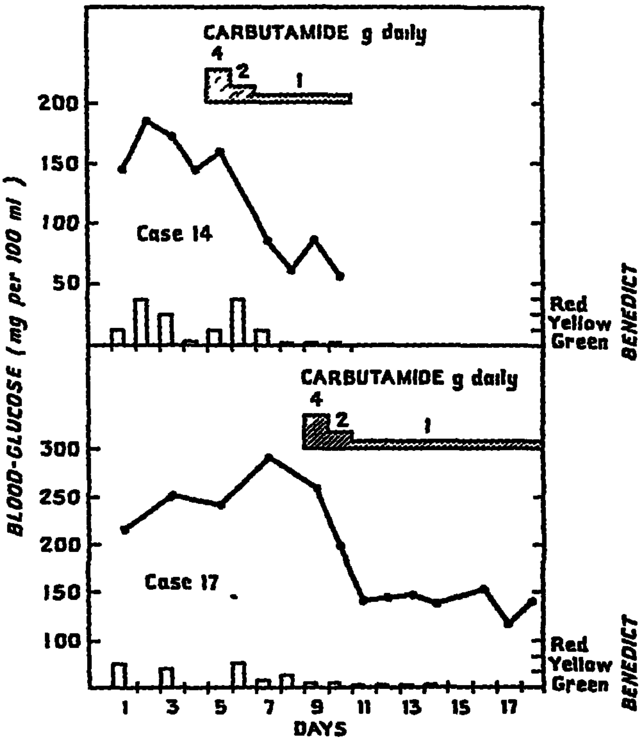

Fig 4—Effects of sulphonamide therapy on glycæmia and glycosuria.

103 mg per 100 ml during treatment (table I) In case 16 the treatment was discontinued and insulin had to be given because of a surgical operation Fig 4 illustrates data from cases 14 and 17

There was no change in the glucose-assimilation coefficient (table I) except a transient improvement during initial treatment in cases 1, 3, and 15 The mean values before treatment, after the first week of treatment, and after prolonged therapy were respectively 0 6, 0 8, and 0 7

The result of the combined intravenous glucose-insulin test was not altered 2 1 before treatment, 2 4 after initial treatment, and 2 7 after protracted treatment

The insulin tolerance tests showed important changes during treatment the hypoglycæmic curves were definitely lower than before sulphonamide treatment Fig 5 shows the mean curves before and after initial treatment

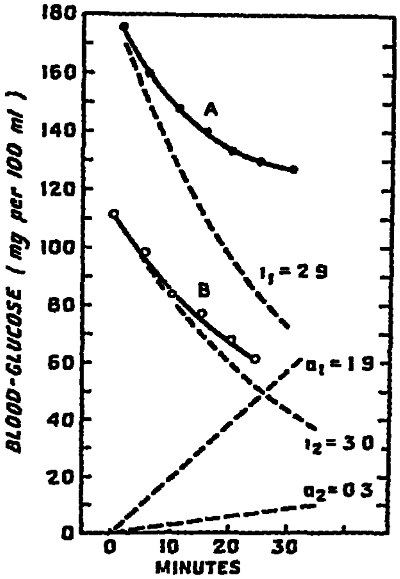

Fig 5—Mean blood-sugar levels A before treatment, B after a week's treatment. Analysis of curves shows factor i unchanged High value of factor a before treatment was much lower after treatment.

Analysis of the individual curves (table II) indicated that, during pretreatment observation, the insulin activity (i = 3 3) was hampered by a large output of glucose by the liver (a = 0 8–3 5, mean 1 5) During treatment the hypoglycæmic insulin effect remained unchanged (3 4 after initial treatment, and 3 5 after prolonged treatment) On the other hand, the output of glucose by the liver decreased considerably (a = 0 after 1 week, and 0 02 after 1–3 months' therapy) Th decrease was constant in all the cases studied In cas 6 and 10 arrest of treatment was followed by a return of factor *a* to its initial value

Discussion

In sulphonamide treated diabetics several workers have not found any sign of improved utilisation of glucose, either by studying postprandial blood glucose levels (Wolff et al 1956), tolerance of oral glucose (Duncan et al 1956), or differences in blood glucose levels between arterial and venous blood (Hunt et al 1956, McKenzie et al 1956)

One of the fundamental characteristics of the diabetic *state is the inability of the tissues to remove blood* glucose at a normal rate (Bastenie 1956) This abnormality is shown by a decrease of the glucose assimilation coefficient The hypoglycæmic sulphonamides do not correct this Duncan (1956) and Duncan et al (1956), using a similar technique, obtained similar results Therefore it can be concluded that, in diabetics, hypoglycæmic sulphonamides do not act by increasing the *output of insulin or by either sparing or boosting* the activity of pre-existent insulin Only in 3 cases was such an effect detectable during initial treatment The transient improvement in the uptake of glucose is probably explained by a stimulation of the β cells, such as has been observed in acute experimental studies by *Loubatieres (1955) and Gepts et al (1956)*

A before treatment
B after initial treatment (5–8 days)
C after protracted treatment (1–3 mos)
*Treatment stopped before test values discarded from statistical analysis

The hypoglycæmic effect of insulin (judged by the combined glucose-insulin test or by the value of factor i calculated from the intravenous insulin test curves) also remained unchanged These observations again seem to rule out a true insulin sparing effect of the sulphonamide

The most interesting observation concerns the considerable constant progressive decrease in the value of factor *a*

According to Soskin and Levine (1946) a very important characteristic of the diabetic state is the absence of the normal control of gluconeogenesis in the liver As is shown in the present investigation and confirmed in more extensive studies by Franckson (1957), during insulin induced hypoglycæmia diabetics do not usually show the depression of the hepatic glucose output observed in healthy people The correction of the

abnormality by the hypoglycæmic sulphonamide may be responsible for the lowering of the fasting blood-glucose level This effect is best explained by the finding that hypoglycæmic sulphonamides inhibit the action of glucose 6-phosphatase (Hawkins et al 1956) If this explanation be the true one, it means that sulphonamide treatment corrects only the end-stage of the diabetic process (i e, the abnormal output of glucose by the liver) and not the diabetes

In the absence of increased production or activity of insulin the gain in weight observed in sulphonamide-treated diabetics on a free diet cannot be explained by increased lipogenesis from enhanced assimilation of glucose Decrease of glycosuria can only partly explain this gain in weight Increase in the amount of pyruvic acid in the blood (Steigerwald et al 1956) may point to re-utilisation in the liver of the newly formed and unexcreted glucose More observations are needed before we can conclude, from the return of the raised blood-cholesterol level to normal (Bohle et al. 1956), that the mobilisation of lipids from the liver is decreased by sulphonamide treatment

The blood-protein pattern, studied before treatment in 8 cases, showed, compared to the values observed in healthy people, a decrease in the percentage of albumin and a slight increase in β and γ globulins Prolonged treatment did not much change the abnormalities, but the possibility exists that, in 3 cases, a low value of the percentage of the albumin fraction was partly corrected by the therapy If this observation is substantiated by further studies, it points to reduced breakdown of protein and resynthesis of albumin in the liver from unexcreted glucose

Summary

18 diabetics (all except 2 being of the obese-aged type) were given carbutamide therapy partly under well-controlled conditions Intravenous glucose-tolerance tests, intravenous insulin tests, and combined intravenous glucose and insulin tests were made before treatment, after initial treatment, and after protracted treatment, and the levels of total lipids, cholesterol, and proteins in the serum were studied

The results show that sulphonamide treatment induces no increased uptake of glucose by the tissues Therefore the improvement of the diabetes cannot be ascribed to an increase of either secretion or activity of insulin

The activity of exogenous insulin remains unchanged Hence it may be concluded that no insulin sparing action is demonstrable

During insulin-induced hypoglycæmia the maintenance of a large output of glucose by the liver is characteristic of diabetes This abnormality is corrected by sulphonamide treatment

The action of carbutamide in diabetes is probably best explained by the discovery of Hawkins et al (1956) that sulphonamides inhibit hepatic glucose 6-phosphatase

Studies on the levels of cholesterol and proteins in the serum are too limited to permit conclusions However, some observations seem to be in keeping with the idea that the unexcreted glucose may be re-utilised in the liver for the synthesis of albumin, and that less protein and less fat are katabolised

ACUTE SPONTANEOUS MEDIASTINAL EMPHYSEMA

S G FLAVELL MATTS*
M B Birm
RESIDENT MEDICAL OFFICER, ROYAL DEVON AND EXETER HOSPITAL

THE term "acute spontaneous mediastinal emphysema" was first used by Hamman (1937), but Laennec (1827) described it under the name of "interlobular emphysema" Thanks largely to the experimental work of the Macklins (1944) its ætiology is now better understood The condition, however, remains uncommon and is still imperfectly described in many textbooks

Ætiology

PORTALS OF ENTRY OF AIR

There are five possible portals of entry of air into the mediastinum

(I) *Through Ruptured Marginal Alveoli*—The Macklins (1944) have shown both experimentally and by clinical correlation that, if a pressure gradient exists between the alveoli whose bases rest against bronchi, bronchioles, blood-vessels, connective tissue septa, and pleura (the so called "marginal" alveoli) and the structures against which they lie, rupture may take place, letting air into the underlying connective tissue, creating pulmonary interstitial emphysema If the escape of air is considerable it will dissect the tissues along the pulmonary blood vessels to the mediastinum If this process continues air accumulates in the mediastinum under ever increasing tension, interferes with the circulation by compression of the great vessels, and embarrasses the heart This tension is relieved by the escape of air into the neck, axilla retroperitoneal tissues, or one or both pleural cavities The conditions which predispose to pulmonary interstitial air were classified by the Macklins (1944) into three groups (*a*) those in which there is first an atelectasis of some part of the lung, followed by overinflation in adjoining regions in the same lung or the opposite lung, (*b*) those in which there is a decreased blood supply to the pulmonary vessels with lowered vascular pressure, often associated with increased intra alveolar pressure or overinflation, and (c) those in which there is a general overinflation of alveoli with or without increased intra-alveolar pressure

---

* Present address Frenchay Hospital, Bristol

(2) *Through Mucosa of Upper Respiratory Tract*.—The mucosa may be injured as a complication of endotracheal anæsthesia (Barrett and Thomas 1944, Jones 1945), trauma, or tracheostomy (Champneys 1884)

(3) *Through apical pleura* as a result of surgery or of accidental trauma (Bowden and Schweizer 1950)

(4) *Along the carotid sheath or the fascial planes of neck* as a complication of block dissection of the neck (Aiken and Smith 1953) or other neck surgery (Bowden and Schweizer 1950)

(5) *From pneumothorax*, which may be spontaneous, traumatic, or artificial (Macklin and Macklin 1944, Davidson 1951)

CLINICAL CAUSES

The following list includes all the conditions (traumatic and non-traumatic) in which mediastinal emphysema has been found or the known predisposing factors may be present (Macklin and Macklin 1944, Aisner and Franco 1949) infectious diseases (infections of upper respiratory tract, measles, tuberculosis, pertussis, pneumonia, influenza, diphtheria, smallpox, &c), space occupying lesions of the lungs or the mediastinum, inhaled foreign bodies, atelectasis in the newborn (due to prematurity or following the inhalation of meconium, mucous secretions, &c , before or after birth), bronchiectasis, bronchial asthma, chronic bronchitis and emphysema, parturition, violent coughing, violent exercise, acts of straining, acute obstructive laryngitis (diphtheria, streptococcal infection) playing of wind instruments, glass-blowing, &c , endotracheal anæsthesia, resuscitation by intratracheal insufflation or with a respirator, positive-pressure inhalation therapy, silicosis, pneumothorax, tracheotomy, cervical surgery, pulmonary infarction, lung blast, caisson disease, hiccup, and trauma to neck or chest

Clinical Features

SYMPTOMS

The severity and nature of the symptoms depends on the degree of distension of the tissues and on the location and accessibility of the escape channels In severe cases the lung, as a consequence of interstitial emphysema, may become extremely voluminous and rigid, causing orthopnœa and dyspnœa

The commonest and most important presenting symptom is pain in the chest (Scott 1937, Miller 1945, Fagin and Schwab 1946, McCabe 1947), which is often mistaken for angina pectoris or for myocardial infarction The onset is usually but not always sudden It is not usually related to respiration but may be worsened by coughing Its location is variable, the commonest sites being precordial or substernal, but it may be felt almost anywhere in the chest It may radiate to neck, shoulders, arms and back The intensity varies from very mild discomfort to severe agonising pain, which may be transient or last several days and usually disappears gradually

Other symptoms include palpitation, sweating, dysphagia, a feeling of fullness in the neck, anxiety, and crackling in the tissues If the air has passed retroperitoneally, there may be pain in the back, if it has passed into the abdomen, there may be abdominal pain

SIGNS

There may be very few physical signs in a mild case, and it seems likely that for this reason, many cases of this type are not diagnosed However, the combination of mediastinal crepitation, decrease or obliteration of cardiac dullness, subcutaneous emphysema, and pneumothorax is pathognomonic

Air in the mediastinum produces sounds that have been described in many different ways (Fagin and Schwab 1946, Aisner and Franco 1949), the commonest terms being "crackling," "clicking" "bubbling," and "crunching" The sounds are usually most easily detected with the patient in the left lateral recumbent position and during the expiratory phase of respiration They can be so faint as to be mistaken for a pericardial friction rub and have been shown to be related to the cardiac cycle (Hoffman et al 1943, Fagin and Schwab 1946) The crunching sound synchronous with systole was originally described by Hamman (1937), is usually known as Hamman's sign, and is regarded as pathognomonic of air round the pericardial sac

Pneumothorax with mediastinal emphysema is nearly always left sided No adequate explanation has ever been offered for this It is present in about 60% of cases

The subcutaneous emphysema is usually in the neck, the supraclavicular and infraclavicular fossæ, and the axillæ Occasionally it may be found elsewhere (Adcock 1943)—in the back, the abdomen, and even the extremities—but this is rare

The temperature and blood-pressure are usually unaffected, unless a cardiac tamponade effect occurs as a result of mediastinal obstruction, in which case the blood-pressure falls considerably This is a sign of grave prognostic significance and indicates that steps should be taken to relieve mediastinal tension

The respirations may be increased, particularly in the presence of pneumothorax, but the tachypnœa is usually mild

The X-ray appearances are typical of those of air in the tissues Air-streaks along fascial planes and pockets of air in the subcutaneous tissues are usually readily detected It is most important to have lateral radiographs of the chest because small pockets of air either behind or in front of the heart may be otherwise missed

There are usually no gross electrocardiographic changes It is said that 25% of cases show positive findings (Aisner and Franco 1949), but no characteristic pattern is present The usual abnormalities that have been described are changes in the T waves, deviation of the ST segments from the iso-electric line, and reduced voltage (Hamman 1939, Miller 1945, Fagin and Schwab 1946, Littman 1946), but pneumothorax per se may produce similar changes (Master et al 1937, Bourne 1940)

Different Diagnosis

All other causes of either acute or subacute pain in the chest have to be excluded angina pectoris, pericarditis, myocardial infarction, pulmonary embolism mediastinitis, dissecting aneurysm of the aorta, pleurisy, intercostal myalgia, &c

The chief difficulties are that the pain is very similar to that of primary cardiac disease, dyspnœa, cyanosis, and distension of the neck veins may be present, and the electrocardiographic changes may simulate an infarct (Hamman 1934, Scott 1937, Miller 1945, McCabe 1947)

However, the diagnosis is usually simplified by the following facts

(1) Mediastinal emphysema commonly occurs in a younger age group

(2) There is no severe shock, fever, tachycardia, hypertension, leucocytosis, or raised erythrocyte sedimentation rate

(3) In most cases some or all of the typical signs of mediastinal emphysema already described are present

Treatment

This is usually only symptomatic, the air being quickly absorbed from the tissues However, in those cases in which increased mediastinal pressure is causing extreme respiratory or cardiac embarrassment the following methods have been suggested

Waring (1944) advised the use of a high pressure chamber to reduce the volume of air in the mediastinum

Cliff (1955) suggested multiple incisions into tissues

When a pneumothorax is present needle aspiration of the thorax has been advised by Gumbiner and Cutler (1941) and Heald and Wilder (1949)

When a tension pneumothorax is present, thoracotomy with continuous underwater drain may prove life saving (Aisner and Franco 1949, Borne et al 1955)

If incision into the tissues is contemplated, the suprasternal notch is the site of choice (Gaudrault and Chalmers 1941, Aisner and Franco 1949) Karns and Daue (1948) recommend mediastinotomy in severe cases Needle aspiration of subcutaneous emphysema has also produced symptomatic relief

Chemotherapy is recommended in all cases, to prevent or treat respiratory infections (Schwartz et al. 1946)

Course and Complications

Mediastinal emphysema is usually benign but may become malignant under the following conditions

(1) When local compression of the blood vessels or of the heart interferes with the circulation

(2) When massed air-bubbles in the pulmonic interstitial tissues splint the lungs in inspiration, making further respiration progressively difficult or impossible

(3) When the pressure in the mediastinum rises too high owing either to blocking of the usual escape routes into the neck and retroperitoneum or to a massive escape of air into the mediastinum

(4) When air escaping into both pleural cavities causes bilateral pneumothorax

(5) When there is serious inflammation in the lungs

(6) When cough or other factors create a tension pneumothorax

(7) When the condition is a sequel to atelectasis of the newborn

Case-reports

Case 1—A boy, aged 4 years, started measles four days before admission For the first two days after the appearance of the rash he was not in any way distressed Then cough with increasing breathlessness developed, the dyspnœa becoming much more acute on the day of admission There was no history of previous illness and no complaint of chest pain.

On examination he was breathless, ill, and slightly cyanosed, with temperature 100 8°F, respirations 60 a minute, and gross surgical emphysema all over his chest and extending into both sides of his neck and face Moist râles were heard on both sides of his chest No clinical evidence of pneumothorax Radiography of his chest showed gross surgical emphysema of his chest wall, mediastinum, and both axillæ (fig 1), consolidation in middle zone of left lung, no pneumothorax Hb 77%

Treatment and Progress—Nursed in an oxygen tent and treated with sedation and full doses of tetracycline the boy steadily improved over the next week, the surgical emphysema becoming absorbed in four days, and subsequent recovery being uneventful

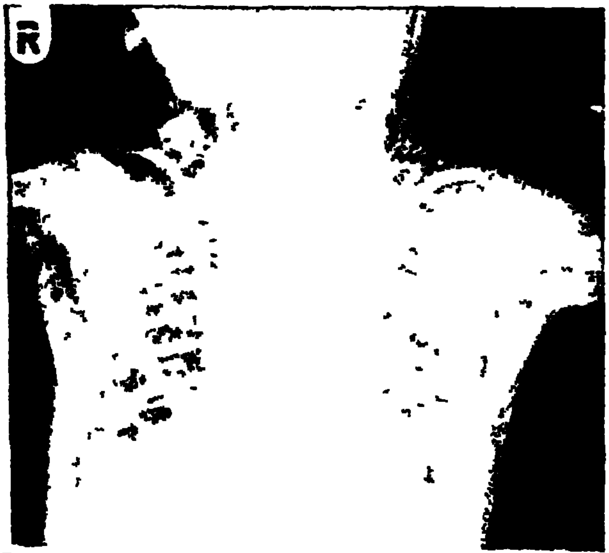

Fig 1—Case 1 gross emphysema of superior mediastinum neck and both axillæ

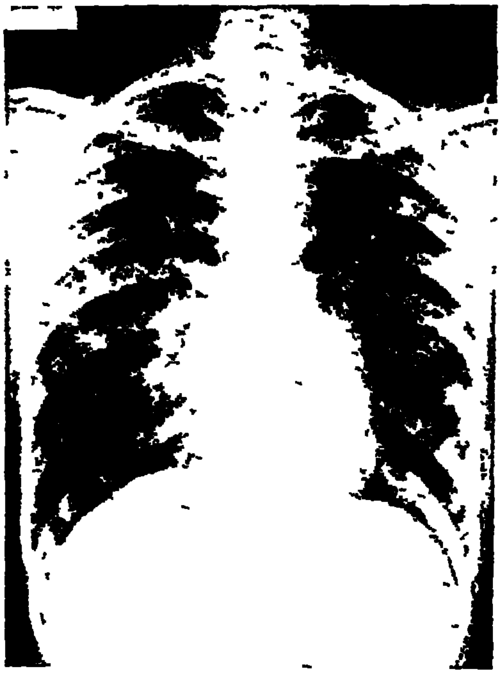

Fig 2—Case 2 air in fascial planes of neck, mediastinum, and axillæ Note characteristic air-streaks in superior mediastinum

Comment—This case would fit well into the Macklins' (1944) group *a* atelectasis due to bronchopneumonia and overinflation due to coughing causing mediastinal emphysema The child was severely ill on admission, his dyspnœa being due partly to bronchopneumonia and partly to interference with respiration by the mediastinal emphysema Nevertheless the condition cleared up rapidly without specific treatment to relieve the emphysema

Case 2—A male bank-clerk, aged 17, had been quite well until just before admission He swallowed a glass of fizzy lemonade and five minutes later suddenly felt a severe constricting pain in his throat, front of chest, epigastrium, and left side

On examination he was pale and anxious but not dyspnœic, with surgical emphysema of his neck and left chest wall a to and fro "pericardial rub," and no evidence of pneumothorax Radiography of his chest showed emphysema of his neck, left axilla, and mediastinum (fig 2), no abnormality of lung fields, no pneumothorax After a barium swallow no abnormality was seen Blood examination showed Hb 97%, white cells 10,000 per c.mm (polymorphs 76%, eosinophils 6%, lymphocytes 17%, monocytes 1%)

Treatment and Progress—A Ryle's tube was passed and left in situ for thirty six hours On rest in bed and penicillin therapy the boy made an uneventful recovery, the surgical emphysema resolving in ten days

Comment—The cause of this mediastinal emphysema is unknown The drinking of fizzy lemonade five minutes before the onset cannot be dismissed The patient was not ill at any time, and there was no need to consider any further treatment than that given The friction noise heard over the precordium was recognised to be due to emphysema around the heart (Hamman's sign) but initially sounded remarkably like a pericardial friction rub

Case 3—A man, aged 35, had six years history of nausea and epigastric pain A barium meal had shown a large active ulcer on the lesser curve of his stomach and persistent deformity of the duodenal cap The patient had not responded to medical treatment and partial gastrectomy was advised

Operation proceeded normally, a Polya-Hofmeister retrocolic gastrectomy being done During the operation the emergency oxygen was accidentally turned on for about one to two minutes with the expiratory valve of the anæsthetic mask which there is a general overinflation of alveoli with or without increased intra alveolar pressure

(2) *Through Mucosa of Upper Respiratory Tract*—The mucosa may be injured as a complication of endotracheal anæsthesia (Barrett and Thomas 1944, Jones 1945), trauma, or tracheostomy (Champneys 1884)

(3) *Through apical pleura* as a result of surgery or of accidental trauma (Bowden and Schweizer 1950)

(4) *Along the carotid sheath or the fascial planes of neck* as a complication of block dissection of the neck (Aiken and Smith 1953) or other neck surgery (Bowden and Schweizer 1950)

(5) *From pneumothorax*, which may be spontaneous, traumatic, or artificial (Macklin and Macklin 1944, Davidson 1951)

CLINICAL CAUSES

The following list includes all the conditions (traumatic and non-traumatic) in which mediastinal emphysema has been found or the known predisposing factors may be present (Macklin and Macklin 1944, Aisner and Franco 1949) infectious diseases (infections of upper respiratory tract, measles, tuberculosis, pertussis, pneumonia, influenza, diphtheria, smallpox, &c), space occupying lesions of the lungs or the mediastinum, inhaled foreign bodies, atelectasis in the newborn (due to prematurity or following the inhalation of meconium, mucous secretions, &c , before or after birth), bronchiectasis, bronchial asthma, chronic bronchitis and emphysema, parturition, violent coughing, violent exercise, acts of straining, acute obstructive laryngitis (diphtheria, streptococcal infection), playing of wind instruments, glass blowing, &c , endotracheal anæsthesia, resuscitation by intratracheal insufflation or with a respirator, positive-pressure inhalation therapy, silicosis, pneumothorax, tracheotomy, cervical surgery, pulmonary infarction, lung blast, caisson disease, hiccup, and trauma to neck or chest

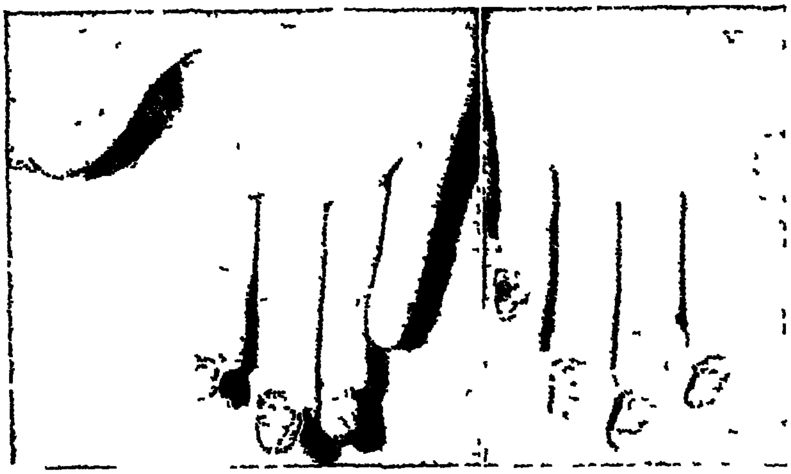
Cliff (1955) suggested multiple

When a pneumothorax is presen thorax has been advised by Gumb Heald and Walder (1949)



Sloughing gangrenous tips of fingers

and Kahn reactions were negative The Donath-Landsteiner reaction was negative The serum electrolyte levels were within normal limits The urine was loaded with red cells and contained granular casts and albumin Cold agglutination tests on the blood were within normal limits

Treatment and Progress —Tolazoline hydrochloride was given intravenously and later intramuscularly without effect Cortisone acetate was also used without producing any improvement The child's general condition remained good He had no pain in his fingers His renal condition slowly improved blood, albumin, and casts disappeared from his urine, and the blood-urea level returned to normal Radiography of his chest showed nothing unusual His toes, the lobes of his ears, and the tip of his nose became normal in the second week His left thumb also resolved completely, but the ends of his other digits became gangrenous and sloughed (see figure) Renal-function tests were normal before discharge, after eleven weeks in hospital

Follow up —When seen ten months after his initial admission the boy was back at school, and had remarkably little disability He had lost the tips of all his digits except the left thumb, but the stumps had healed well, and he could use them normally. The fact that the left thumb was spared considerably lessened the resulting disability

This case is regarded as one of arterial damage due to sensitivity to sulphadimidine Schmid (1953) described a case in an adult with peripheral symmetrical gangrene of this type but rather more severe, which he attributed to sensitivity to a sulphonamide and penicillin In the present case the boy did not have penicillin until after hæmaturia was observed, and the peripheral gangrene followed in four days Hence it seems likely that the damage was done before penicillin was given

My thanks are due to Mr J MacGouran, M S.R , for the photographs

Medical Societies

ROYAL SOCIETY OF MEDICINE

Effects of Smoking

THE section of medicine met on Feb 26, with Dr G E BEAUMONT, the president, in the chair, to discuss the physiological and medical effects of smoking

Prof J H BURN, F R S (Oxford), described experiments (many of them carried out in his laboratory) on the cardiovascular effects of nicotine He first referred to the statements made about the amount of nicotine yielded by cigarettes, and said that Ling and Wynn Parry had found that the smoke entering the mouth from one cigarette contained not more than 1 0 mg , while the amount absorbed when inhaling was about 0 3 mg

Smoking, by sympathetic stimulation through the stellate ganglion and the production of adrenaline, increased the heart rate and raised the blood-pressure by about 10–20 mm Hg (more in hypertensive patients) It caused vasoconstriction in the skin, shown by a diminution of blood flow in the warm hand on plethysmography That this action was peripheral, and not entirely ganglionic, had been shown by perfusing the denervated ear of a rabbit through a cannula in the artery and measuring the *venous outflow* Even in the absence of ganglia, the vasoconstrictor effect was blocked by hexamethonium and reversed by tolazoline The effect might be due to release of adrenaline or noradrenaline from local chromaffin tissue, which would account for the ill effects of smoking in thrombo angiitis even after sympathectomy

The direct effect of nicotine on the coronary arteries was to dilate them, but the constriction caused by vasopressin (through nicotine's stimulation of the supraoptic nucleus) might outweigh this effect Vasopressin had been recovered from the urine after cigarette smoking Nicotine might directly affect the myocardium, which contained noradrenaline and possibly chromaffin tissue After smoking the T wave of the electrocardiogram was flattened , there were changes in the ballistocardiogram only in patients with coronary artery disease Ectopic rhythms were sometimes caused Filter-tips did not abolish these effects Some tolerance to the antidiuretic effect of nicotine might be seen in smokers, but as we grew older we might lose our power to metabolise nicotine Nicotine stimulated peristalsis , the mechanism was not clear

Dr RICHARD DOLL said that 20 retrospective studies had shown a significant association between smoking cigarettes and lung cancer The association held only for oat cell, squamous cell, and undifferentiated carcinomas, and not for adenocarcinomas Two prospective studies were now in progress Among British doctors questioned in 1951 as to their smoking habits, early results had shown sharp differences in the death-rate from lung cancer , the incidence was low in non-smokers but increased as the number of cigarettes smoked increased The association with pipe smoking was less striking Similar trends, though much less marked, were seen in the death-rates from coronary thrombosis, and from other respiratory diseases, where the trend was chiefly due to an association with bronchitis Other types of cancer and other diseases showed no trend in either direction Smokers who had given up smoking had a lower mortality from lung cancer than those who had not A similar study was being made in the United States by Hammond and Horn on 200,000 men The results so far reported indicated that the death rate from lung cancer was ten times as great in cigarette smokers as in non smokers

Dr Doll discussed and dismissed possible causes of bias It had been suggested that the diagnosis of lung cancer was made more often in smokers , but if only histologically proven cases were accepted, the association with smoking was even greater than in the whole series An effect due to selection of an unrepresentative sample of men, because of a tendency of non smokers to reply more readily than heavy smokers to questions about smoking habits, would be expected to apply to all diseases, and the effect would wear off in time, whereas the trend had been about the same in each year of the British investigation and was becoming greater in the almost closed, thus giving full pressure of oxygen in the lungs The surgeon then found much surgical emphysema in the mesentery of the transverse colon Most of the mesentery was emphysematous, but during the operation, which continued to proceed normally, could be felt to be rapidly resolving The patient was taken back to the ward and made an excellent recovery Slight surgical emphysema of the neck was detected, but this quickly resolved in one to two days There were no signs in the chest and no evidence of pneumothorax

Comment —The cause of the emphysema in this case could well be the overinflation of the alveoli with increased intra alveolar pressure—the Macklins' (1944) group c— due to the high oxygen pressure in the lungs during anæsthesia The rapidity of resolution of the surgical emphysema could be due to the speed in which oxygen is normally absorbed by the tissues (considerably quicker than the nitrogen in normal air) The patient had no symptoms from his emphysema and at no time was made ill by it The mediastinal emphysema here escaped mainly into the retroperitoneal tissues and only slightly into the neck This case is of interest because of the unusual way in which the mediastinal emphysema arose and the unusual escape route for the air

Discussion

Although mediastinal emphysema is a well recognised complication of trauma to neck and chest and of neck surgery, its spontaneous or non-traumatic origin is not so widely realised It is quite possible, in view of the multiplicity of predisposing factors and the common occurrence of some of them, that minimal examples of this condition may not be always diagnosed, and in this connection it is emphasised that a postero anterior radiograph of the chest may not show air in front or behind the heart and great vessels Only a lateral view can virtually exclude mediastinal emphysema, and such a view should always be taken when a patient has an unexplained chest pain

An interesting point in the present cases is the absence of pneumothorax Of 50 published cases (Hamman 1934, 1937, 1939 McGuire and Bean 1939, Kirshner 1939, Morey and Sosman 1939, Wolff 1940, Matthews 1941, Pinkney 1941, Styron 1941, Caldwell 1941, Miller 1941, Murphy and Zeis 1942, Griffin 1942, Meek 1942, Kellogg 1942, Dassen and Fongi 1942, Adcock 1943, Greene 1943, Lintz 1943, Munroe and Webb 1943, Hoffman et al 1943 Israel 1943, Miller 1944, Fagin and Schwab 1946, Schwartz et al 1946, Cliff 1955) 30 had a left sided pneumothorax The coexistence of a pneumothorax seems to make the prognosis worse, although in most of the published cases the pneumothorax was small

The term "spontaneous" was originally used because no cause was known Nowadays, however, a predisposing cause can be found in most cases, but occasionally (as in case 2) there is no obvious cause The term "spontaneous," however, should be retained to denote that the condition is not due to trauma

Summary

Three cases of non traumatic mediastinal emphysema are reported because of their relatively mild nature, minimal physical signs (in two cases), ætiology, and rapid recovery

Two of the cases could be assigned to known causes, but the cause of the third is unknown

I wish to thank Dr F S W Brimblecombe and Dr C J Fuller for advice and encouragement Dr A J Daly, Mr K P S Caldwell and Dr W J Walter for permission to publish case reports Mr R Dyson for photographs and the librarian of the B M A library for help with the literature

SYMMETRICAL PERIPHERAL GANGRENE AS A TOXIC REACTION TO SULPHAMEZATHINE AND PENICILLIN

J M BARBER
M D Belf, M R C P E
CONSULTING PHYSICIAN, NORTH DOWN HOSPITALS

Y A MACILWAINE
M D Belf
PATHOLOGIST, ARDS HOSPITAL, NEWTOWNARDS, CO DOWN

VERY many toxic reactions to sulphonamides and to penicillin have been described, but symmetrical gangrene appears to be extremely rare

A boy, aged 12 years, was admitted on Feb 20, 1956 There was nothing significant in the family history, in particular no history of allergy He had had measles, mumps, and chickenpox Two weeks before admission he developed otitis media This was treated with sulphadimidine 2 g initially followed by 1 g four hourly for seven days His ear responded satisfactorily, but at the end of the week he had painless hæmaturia Penicillin was substituted for the sulphadimidine Four days later the tips of the boy's ears, the end of his nose, and the tips of all his fingers and toes were cyanosed and became gradually worse Penicillin was withheld, and he was admitted to hospital

On admission he was not distressed His temperature was 99 4°F He had incipient gangrene of the tips of all his fingers and, to a much less degree, his toes The digits, the lobes of his ears, and the extreme tip of his nose were blue and cold He had gross hæmaturia There were no abnormal physical signs in heart, lungs, abdomen, and central nervous system

Investigations —Hb 9 2 g per 100 ml , red cells 3,300,000 per c mm , packed cell volume 31%, mean corpuscular volume 95 c μ, mean corpuscular Hb concentration 31%, white cells 15,600 per c mm (neutrophils 79%, eosinophils 3%, monocytes 2%, lymphocytes 16%) There was nothing abnormal in the blood films The serum bilirubin was normal The blood urea was 60 mg per 100 ml The Wassermann

Sloughing gangrenous tips of fingers

and Kahn reactions were negative. The Donath Landsteiner reaction was negative. The serum electrolyte levels were within normal limits. The urine was loaded with red cells and contained granular casts and albumin. Cold agglutination tests on the blood were within normal limits.

Treatment and Progress.—Tolazoline hydrochloride was given intravenously and later intramuscularly without effect. Cortisone acetate was also used without producing any improvement. The child's general condition remained good. He had no pain in his fingers. His renal condition slowly improved. blood, albumin, and casts disappeared from his urine, and the blood-urea level returned to normal. Radiography of his chest showed nothing unusual. His toes, the lobes of his ears, and the tip of his nose became normal in the second week. His left thumb also resolved completely, but the ends of his other digits became gangrenous and sloughed (see figure). Renal-function tests were normal before discharge, after eleven weeks in hospital.

Follow up.—When seen ten months after his initial admission the boy was back at school, and had remarkably little disability. He had lost the tips of all his digits except the left thumb, but the stumps had healed well, and he could use them normally. The fact that the left thumb was spared considerably lessened the resulting disability.

This case is regarded as one of arterial damage due to sensitivity to sulphadimidine. Schmid (1953) described a case in an adult with peripheral symmetrical gangrene of this type but rather more severe, which he attributed to sensitivity to a sulphonamide and penicillin. In the present case the boy did not have penicillin until after hæmaturia was observed, and the peripheral gangrene followed in four days. Hence it seems likely that the damage was done before penicillin was given.

My thanks are due to Mr J. MacGouran, M.S.R., for the photographs.

Medical Societies

ROYAL SOCIETY OF MEDICINE

Effects of Smoking

THE section of medicine met on Feb. 26, with Dr G. E. BEAUMONT, the president, in the chair, to discuss the physiological and medical effects of smoking.

Prof. J. H. BURN, F.R.S. (Oxford), described experiments (many of them carried out in his laboratory) on the cardiovascular effects of nicotine. He first referred to the statements made about the amount of nicotine yielded by cigarettes, and said that Ling and Wynn Parry had found that the smoke entering the mouth from one cigarette contained not more than 1.0 mg., while the amount absorbed when inhaling was about 0.3 mg.

Smoking, by sympathetic stimulation through the stellate ganglion and the production of adrenaline, increased the heart rate and raised the blood-pressure by about 10–20 mm. Hg (more in hypertensive patients). It caused vasoconstriction in the skin, shown by a diminution of blood flow in the warm hand on plethysmography. That this action was peripheral, and not entirely ganglionic, had been shown by perfusing the denervated ear of a rabbit through a cannula in the artery and measuring the venous outflow. Even in the absence of ganglia, the vasoconstrictor effect was blocked by hexamethonium and reversed by tolazoline. The effect might be due to release of adrenaline or noradrenaline from local chromaffin tissue, which would account for the ill effects of smoking in thrombo-angiitis even after sympathectomy.

The direct effect of nicotine on the coronary arteries was to dilate them, but the constriction caused by vasopressin (through nicotine's stimulation of the supraoptic nucleus) might outweigh this effect. Vasopressin had been recovered from the urine after cigarette smoking. Nicotine might directly affect the myocardium, which contained noradrenaline and possibly chromaffin tissue. After smoking the T wave of the electrocardiogram was flattened; there were changes in the ballistocardiogram only in patients with coronary-artery disease. Ectopic rhythms were sometimes caused. Filter-tips did not abolish these effects. Some tolerance to the antidiuretic effect of nicotine might be seen in smokers, but as we grew older we might lose our power to metabolise nicotine. Nicotine stimulated peristalsis; the mechanism was not clear.

Dr RICHARD DOLL said that 20 retrospective studies had shown a significant association between smoking cigarettes and lung cancer. The association held only for oat-cell, squamous cell, and undifferentiated carcinomas, and not for adenocarcinomas. Two prospective studies were now in progress. Among British doctors questioned in 1951 as to their smoking habits, early results had shown sharp differences in the death-rate from lung cancer; the incidence was low in non-smokers but increased as the number of cigarettes smoked increased. The association with pipe smoking was less striking. Similar trends, though much less marked, were seen in the death rates from coronary thrombosis, and from other respiratory diseases, where the trend was chiefly due to an association with bronchitis. Other types of cancer and other diseases showed no trend in either direction. Smokers who had given up smoking had a lower mortality from lung cancer than those who had not. A similar study was being made in the United States by Hammond and Horn on 200,000 men. The results so far reported indicated that the death-rate from lung cancer was ten times as great in cigarette smokers as in non-smokers.

Dr Doll discussed and dismissed possible causes of bias. It had been suggested that the diagnosis of lung cancer was made more often in smokers; but if only histologically proven cases were accepted, the association with smoking was even greater than in the whole series. An effect due to selection of an unrepresentative sample of men, because of a tendency of non-smokers to reply more readily than heavy smokers to questions about smoking habits, would be expected to apply to all diseases and the effect would wear off in time, whereas the trend had been about the same in each year of the British investigation and was becoming greater in the

American investigation It was unlikely that smoking merely determined the site of a cancer which would have developed elsewhere if the patient had not smoked, because there was no reduction in the incidence of cancer at other sites in heavy smokers

Another suggestion was that the results arose because heavy smoking was commoner in cities—i e, among those more exposed to atmospheric pollution But the figures showed that, so far as British doctors were concerned, heavy smoking was in fact as common in the country as in the city, and non smoking as uncommon, thus atmospheric pollution was not the factor Another suggested factor was alcohol, since heavy drinkers were often heavy smokers, but it had been shown that there was no significant difference in the prevalence of lung cancer between drinkers and abstainers if smoking habits were kept constant

The mortality-rate from lung cancer had risen with the consumption of cigarettes, but about twenty years later Cigarette consumption in this country had been relatively constant since 1946, and the annual increase in the number of deaths from lung cancer might be expected to cease *in the course of the next one or two decades* There was in general a good correlation between the death-rate from lung cancer and the cigarette consumption in different countries, though the death rate was higher in Britain and lower in the United States than would be expected from comparison with other countries

Hyperplasia and metaplasia of the bronchial epithelium had been shown to be commoner in smokers than in non-smokers, and 3 4 benzpyrene (which has been found in tobacco tar) had produced similar changes in human foetal lung in tissue culture

Dr **Neville Oswald** looked at the question from a clinician's point of view He said that smoking often made angina worse and always made thrombo angiitis worse Swallowing excessive tracheal secretion might explain the adverse effect of smoking on peptic ulcer He wondered whether there was a threshold beyond which smoking caused lung cancer A study of Civil Servants had shown only a slight trend towards a higher incidence of mild respiratory symptoms or bronchitis in smokers than in non smokers Many patients seen at the Brompton Hospital on account of bronchitis had given up smoking and felt better for it

In the discussion, Dr W C **Boake** (Melbourne) reported an investigation of a group of 118 ordinary adults in Cleveland, Ohio, for whom careful records of common acute respiratory illnesses had been kept for up to six years There was no correlation between smoking and the incidence or severity of these illnesses Of the symptoms, he confirmed the common impression that smokers coughed more, though they had no more sputum They had fewer sore throats—perhaps because they had one all the time and did not notice them Mr F A **Williamson Noble** said that the carbon monoxide produced by smoking appreciably increased the oxygen need of aviators Dr **Horace Joules** pointed out that effective legislation about chimney sweep's cancer did not come till a hundred years after the discovery of its cause, and predicted a million deaths from lung cancer in this century in England and Wales unless people stopped smoking

The **President** observed that 15 of the audience had been smoking at the start of the discussion, but only 1 at the end

Ætiology of Pre-eclampsia

A meeting of the section of obstetrics and gynæcology on Feb 22, with the president, Mr **Alan Brews**, in the chair, discussed the causes of pre-eclampsia

Prof J C **McClure Browne** said there were as many theories on this subject as there were obstetricians Eight or nine years ago the work of Baker [1] and Bastiaanse and Mastboom [2] had revived interest in the placenta as the supposed starting point of the chain of events which culminated in eclampsia If placental ischæmia could indeed cause a rise in systemic blood-pressure, it was logical to suppose that pre eclamptic toxæmia would develop when the pregnant uterus was overdistended, as in hydramnios and twins, and sometimes in the primigravida Professor Franklin and Mr Sophian had shown that distension of the pregnant rabbit uterus would cause a renal cortical ischæmia, which could be held to account for the albuminuria and so on But McGaughey and his colleagues [3] had lately failed to demonstrate a specific uterorenal reflex in the dog

Up till 1948, no-one had shown that placental ischæmia existed in pre eclampsia, and Professor Browne described experiments which he and his colleagues performed to decide this point When the placenta was situated anteriorly it was possible to inject a tracer dose of ^{24}Na into the choriodecidual space and to record the time taken for it to be cleared by the maternal placental circulation In a normal woman between 38 and 40 weeks the mean half-period for clearance was 21 seconds, in pre eclampsia it was 65 seconds In essential hypertension, however, where the hypertension has antedated the pregnancy the same degree of ischæmia was found It was concluded, therefore, that the placental ischæmia was the result and not the cause of the hypertension of pre eclamptic toxæmia We were astounded, Professor Browne declared, at the big reduction in maternal placental blood-flow when hypertension was present, but careful rescrutiny of the methods and results had confirmed the findings

The clear evidence that hypertension causes placental ischæmia, and not the other way round, suggested that the uterine-tension theory of pre eclampsia was wrong The exponents of this theory held that the tension of the primigravid uterus, or the presence of twins or hydramnios, produced placental ischæmia and if the intra uterine tension was reduced (e g, by rupturing the membranes), *then the ischæmia was diminished* and the toxæmia immediately improved But this was certainly not Professor Browne's experience in clinical obstetrics there were many instances of serious deterioration after surgical induction in pre eclamptic toxæmia

Dr **Norman Morris** said that Professor Browne's pioneer work had stimulated Dr Payling Wright and himself [4] to investigate the clearance rate of ^{24}Na from the myometrium 0 3–0 4 ml of ^{24}Na Cl, with an activity of between 5 and 10 microcuries, was injected into the myometrium A Geiger counter was then arranged over the site of injection and the rate of clearance of the ^{24}Na was recorded Normotensive women gave an average time to half value of 4 1 min In mild pre eclampsia (diastolic pressure 85–95 mm Hg) the average was 7 7 min, and in severe pre-eclampsia (diastolic over 95) it was 15 3 min These figures strongly suggested that pre eclampsia was associated with a significant reduction in myometrial blood-flow and that this was probably the main cause of the reduced placental blood flow observed by Professor Browne Further observations showed how the clearance-rate seemed to be progressively reduced as the blood-pressure rose Lowering the blood pressure with protoveratrine improved the clearance rate Experiments were then designed to determine the effect of exercise upon the clearance rate of ^{24}Na both from the myometrium and from the anterior belly of the quadriceps The results suggested that during exercise blood-flow to the uterus was reduced but quickly returned to normal when the exercise stopped This reduction in uterine flow was probably the result of a generalised splanchnic vasoconstriction, since, in the non-pregnant, exercise also reduced the renal blood-flow

[4] Morris N et al *Lancet*, 1955 i, 323, *Ibid*, 1956, ii, 481

Turning to the clinical significance of these findings, Dr Morris pointed out that in pre eclampsia it was well established that rest usually prevented deterioration while physical activity caused exacerbation Reduction of salt intake was also beneficial, though the reasons for this were not clear The precise origin of the pressor mechanism was also unknown Mr Sophian thought it originated largely from the kidney, others thought it came from the placenta, still others believed that it might arise in the adrenal or pituitary The harmful effect of exercise strongly suggested that the increased splanchnic vasoconstriction that resulted in some way also further stimulated and perpetuated the production or activity of the pressor factor, thus establishing a vicious cycle Many women progressed to moderate or even severe pre eclampsia before they were seen Dr Morris wondered what would happen if all primigravidæ over 30 weeks were treated as though they already had mild pre eclampsia might not then the pattern of severity of pre eclampsia be much changed ?

Dr Morris found it hard to accept that pre eclampsia was primarily due to myometrial resistance to stretch or to a uterorenal reflex Pre eclampsia was certainly *not* associated with a consistently increased intra uterine pressure If the stretch theory was right, why was it that twins, acute hydramnios, and pregnancy in a rudimentary horn did not always give rise to pre eclampsia ? Furthermore why could pre eclampsia occur in association with an extra-uterine pregnancy ?

Mr JOHN SOPHIAN's theme was cortical renal ischæmia and the stimulus that provoked it—the uterorenal reflex initiated by stretching of the resisting uterine muscle Discussing renal hæmodynamics, he said that it had hitherto been held that there was a uniform single circulation in the kidney and that the regulation of glomerular filtration depended on the ratio of afferent to efferent arteriolar resistance But Pappenheimer had lately emphasised the fact that, since the afferent arteriole was shorter and at least 50% wider than the efferent, its effective resistance must be small compared with the efferent resistance Pappenheimer had also disproved the explanation of extraction-ratio values put forward by the Homer Smith school, and his observations provided a new and accurate yardstick for determining hitherto occult changes in renal circulation —changes responsible for the ischæmia which, in Mr Sophian's view, underlay the pre eclamptic process To explain renal hæmodynamics, two intrarenal circulatory processes must be envisaged one offered a greater resistance to blood flow than the other, and it was not very efficient in extracting circulating substances and consequently had a smaller oxygen need Pappenheimer's two circulations were in parallel, whereas the Trueta dual circulation was in series, but there were many points of similarity between the two This idea of a dual intrarenal circulation immediately shed new light on pre eclampsia according to this thesis, ischæmic and anoxic changes were occurring occultly in the kidney —changes that explained the œdema, albuminuria, and hypertension of pre eclampsia

Turning to the part played by the uterus in initiating the renal changes, Mr Sophian said he had no doubt that myometrial resistance to stretch explained the events Dysmenorrhœa, uterine inertia, and pre eclampsia seemed to arise preponderantly in women whose cervix has not been stretched by a full time fœtus—suggesting that an intact cervical innervation had a share in their production This innervation might be responsible for keeping up isometric tension in first pregnancies and thereby adding to the resistance to stretch Proof of this increased tension was partly derived from biochemical studies and partly from tocometric tracings Moreover, Reynolds had pointed out that whereas the multiparous uterus tended to become globular after mid-pregnancy, the primigravid organ became elongated, connoting a rise of tension He had also shown the existence of such heightened tension in toxæmia Increase in circulating adenosine in toxæmia was shown to indicate both uterine muscle ischæmia and an increased isometric tension of the muscle

In addition to the histological proof of the uterorenal reflex, biochemical evidence had lately been provided by McGaughey et al ,[3] who had shown that a mean reduction of 23% in the urinary clearance of *p*-aminohippuric acid followed acute distension of the uterus in dogs—a clear indication of reduced renal plasma flow induced by the reflex

The reduced circulation observed in the uterus of pre eclampsia was due in the first place to the resisting tension in its walls and later (and additionally) to the constriction of its vessels provoked by the pressor substances from the ischæmic kidney, which also responded similarly to exercise, as Dr Morris had indicated As for the effects of treatment, release of liquor relieved uterine tension, the uterorenal reflex subsided, and the toxæmia abated Similarly, the death of the fœtus relieved the toxæmia because the resulting flaccidity of the fœtus and the reduction in the turgescence of the myometrial circulation lessened both stretch influences and uterine tone, and thus improved the mother's condition

Mr Sophian discounted the rôle of the placenta because (*a*) toxæmia could recur during labour, days after its quiescence on the death of the fœtus, and (*b*) hormones were not of primary ætiological significance [5] These facts disproved toxin production and abnormal hormonal action by the placenta There was further proof of this although the interstitial-fluid space was 40% larger in the toxæmic than in the healthily pregnant woman, this space in the fœtuses of both toxæmic and normal mothers showed no expansion Yet there was evidence, in the mastitis of the newborn males, that maternal œstrogen passed the placental barrier

Reviews of Books

Experimental Design and its Statistical Basis

D J FINNEY, M A, SC D, F R S, reader in statistics in the University of Aberdeen London Cambridge University Press 1955 Pp 169 30*s*

ALTHOUGH his early experience in the development of experimental design lay in the field of agriculture, Dr Finney has written an excellent introduction to the tactics of experimentation for scientists in general which should be valuable to medical research-workers in particular

The mathematical background is minimal, but the rationale of the science of experimental design in the Fisherian tradition is clearly set out The compact style requires close attention, but the reader will be rewarded by a clear understanding of the notions underlying such experimental designs as randomised blocks and Latin squares The relevance of these simpler designs to medicine is made obvious by some well chosen examples of clinical trials and tests of experimental or observer variation Experimentation in genetics and the more complex designs involving confounding are briefly covered A chapter on sequential experiments, including an outline of " staircase methods " in bio assay, should stimulate pharmacologists to reconsider their plans for laboratory assessments of therapeutic agents

This text can be confidently chosen by the medical scientist as a primer in the experimental method

Marshall's Physiology of Reproduction

3rd ed Vol 1 part 1 Edited by A S PARKES, D SC, SC D, F R S National Institute for Medical Research, London London Longmans, Green 1956 Pp 688 150s

THE second volume of the new edition of this enormous and useful book has already appeared The first volume has itself undergone fission

Part 1 contains, in addition to Marshall's own original first chapter, chapters on the morphology and anatomy, reproductive cycle, œstrous cycle, ovarian changes, and changes in the non-pregnant female adnexa, throughout the vertebrates The matter is presented phylogenetically in each chapter, and there is little overlapping between the morphological and physiological accounts The material reviewed is drawn mainly from publications before 1948 The time lag is unfortunate, but not excessive in view of the size of the task and the fact that all the contributors are active in research A 4th edition is already in preparation

The "perennial controversy" about the neogenesis of ova in adult mammals, which has been conducted for so long between Dr Parkes on the one hand and Sir Solly Zuckerman, his leading contributor, on the other, is nicely but rather briefly reviewed by Dr F W R Brambell in the chapter on ovarian changes

The merits of this book as a source for all biological workers are already recognised, and in the new edition they are if anything increased Human reproduction is treated in its strictly comparative context, but the book ought to be consulted regularly by any medical worker who attempts to supplement his understanding of human physiology by experiments on animals Perhaps the chief merit of such extended reviews is that they hammer home the diversity of animal physiology and the dangers and profits of analogy—both are important in medicine, if we remember the long period of obstruction in endocrinology which resulted from the confusion between œstrous and menstrual cycles, and which Marshall himself did much to end The corresponding defect of large reviews is that they tend to perpetuate error by diverting inquirers from the original papers, but the choice of contributors to this book and the excellent bibliographies reduce this risk Even at the cost of further increase in size and price, a growing need becomes evident for the inclusion of a parallel treatment of reproductive behaviour The new volume is expensive but indispensable to those who deal with its subject-matter

Chirurgie orthopédique des paralysies

R MERLE D'AUBIGNÉ, professeur de clinique chirurgicale orthopédique et réparatrice à la Faculte de Médecine de Paris, J BÉNASSY and J O RAMADIER, chirurgien assistants des Hôpitaux de Paris Paris Masson 1956 Pp 430 4200 fr

THIS is the first volume of the *Collection de Chirurgie Orthopedique* planned by that good friend of this country, Prof Merle d'Aubigne, and if the standard of this book can be maintained the subsequent fourteen volumes can be sure of a warm welcome The book is directed towards the young surgeon who wants to know not just what could be done but rather what should be done for any particular condition It is essentially concerned with treatment, each chapter dealing with the mechanical and dynamic aspect of its subject All standard procedures are fairly assessed Poliomyelitic paralyses are not included as they are to be the subject of a separate volume This well-balanced book will prove most useful to the surgeon confronted with these often difficult exercises in surgical judgment

Lectures in Immunochemistry

MICHAEL HEIDELBERGER, PH D, emeritus professor of immunochemistry College of Physicians and Surgeons, Columbia University, New York New York Academic Press London Academic Books 1956 Pp 150 32s

THIS is a collection of lectures delivered during the past ten years in Tokyo, Paris, Marburg, and New Brunswick

The topics range from general aspects of immunity to quantitative analytical methods of serology The lectures are reproduced as they were delivered, and they have not been edited to weld them into a coordinated whole Characteristically Heidelberger remarks "this small volume is an indolent man's response to the urging of his friends that he write a book" *All serious students of immunity will welcome* these discussions of subjects with which the author has been familiar so long Heidelberger's interest in immunology began with coöperation with O T Avery in studying the specific polysaccharides of pneumococci, extended to the development of quantitative analytical methods in serology, and included searching studies of complement, whose functions in immunity reactions are still something of a mystery

Neoplasms of the Domesticated Mammals

E COTCHIN, M R C V S, department of pathology, Royal Veterinary College, London Review series no 4 of the Commonwealth Bureau of Animal Health, Farnham Royal, Bucks 1956 Pp 100 20s

VETERINARY surgeons have not, in the past, been greatly interested in pathology Recently, however, a new enthusiasm for this subject has arisen in teaching schools

The purpose of this book is threefold to interest veterinary surgeons and pathologists in the subject, *to encourage the* study of material which, as Prof R A Willis pointed out in 1948, is largely wasted, and to provide a background of knowledge (including references to published work) about tumours in animals for the use of experimentalists, who often have to decide whether a certain neoplasm has been induced by the treatment employed

The scope of the book is limited to tumours in the horse, ox, sheep, pig, dog, and cat A series of 930 spontaneous tumours in rabbits, guineapigs, rats, and mice has recently been reviewed by C Tamaschke (*Strahlentherapie*, 1955, 96, 150) Each of the 1000 works listed in the bibliography has been seen by the author, who adopts a reasonably critical attitude to incomplete or misleading descriptions—which must have been very difficult in a field where "Many of the papers consulted were of a rather anecdotal nature"

The nomenclature, based on that proposed by R A Willis (*Pathology of Tumours* London, 1948) *for human tumours* is simple and comprehensive The tumours of each system are considered in paragraphs relating to the various species one by one This method tends rather to break the sequence of the text but is useful for reference to the facts about a particular species The bibliography is good, and there is an index

This book will be a valued addition to pathological reference libraries, and it will be hailed with gratitude by all experimentalists whose field in any way touches neoplastic diseases

Classics in Arterial Hypertension

ARTHUR RUSKIN, M D, F A C P, associate professor of internal medicine, University of Texas Medical Branch consultant to the U S Public Health Service Hospital Galveston, Texas Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1956 Pp 358 72s

THIS compilation will be of great interest to all physicians with a scholarly interest in the unsolved problems of hypertension in our ageing population

Workers quoted range from Stephen Hales to Harry Goldblatt, and include 19th century British contributions by Bright, Johnson, Gull, Sutton, Gowers Albutt, and Mahomed Writings of Korotkoff Riva Rocci Tigerstedt, and many others are included While many will welcome the opportunity to read the *ipsissima verba* (*even in translation*), some may be surprised at the lack of balance between the selections and the omissions Mahomed's paper on scarlatinal nephritis written at the age of 25, is given at length, while his later and more interesting paper dealing with essential hypertension is left out Volhard and Fahr get short mention but are not quoted Potain's work on hypertension is sketched but the extract from his paper on gallop rhythm admittedly of great excellence, is rather outside the main theme

Dr Ruskin has produced an appetiser We hope that he or a colleague will later provide a greater variety of morsels

THE LANCET

LONDON SATURDAY, MARCH 9, 1957

Hypophysectomy for Cancer

HYPOPHYSECTOMY was first described for breast cancer in 1952–53,[1,2] not long after HUGGINS and BERGENSTAL[3] had established total adrenalectomy as a practical procedure in 1951 Adequate data are now beginning to accumulate so that the relative value of the two operations can be assessed Hypophysectomy has several theoretical advantages over adrenalectomy By removing the gonadotrophic and adrenocorticotrophic stimuli, it might be expected to eliminate œstrogens from the body more completely than is possible by combined oophorectomy and adrenalectomy Œstrogens and pregnanediol have been found in the urine even after oophorectomy and adrenalectomy,[4,5] which suggests that accessory adrenal or other œstrogen-secreting tissue may be left behind, and accessory adrenal tissue has in fact been demonstrated in the region of the cœliac artery[6] and in the broad ligament[7] On the other hand, STRONG et al[5] did not detect any increase in the output of œstrogens and pregnanediol in patients who had undergone oophorectomy and adrenalectomy and were then given an intravenous infusion of corticotrophin Actually, even hypophysectomy does not necessarily eliminate œstrogens from the urine[4], but the elimination of prolactin may be of equal importance[8,9], and the elimination of growth hormone might be a further advantage of hypophysectomy for breast cancer Growth hormone is known to increase the incidence of certain tumours in rats, whereas hypophysectomy reduces it[10,11] This influence of growth hormone has been observed in a patient with breast cancer who was in a state of remission after bilateral oöphorectomy and adrenalectomy, followed by hypophysectomy injections of growth hormone for 18 days led to a steady increase in urinary calcium and phosphate excretion, in the same ratio as that of calcium to phosphate in bone, suggesting that the growth hormone had induced bone destruction by stimulating the growth of bone metastases[12–14] Another reason for the trial of hypophysectomy in the treatment of malignant disease is that only 13 instances have been reported of cancer in association with panhypopituitarism, and in none of these did the growth arise in the breast or ovary[15] The only theoretical objection to hypophysectomy is that cancer of the female breast and genital tract occurs more often in hypothyroidism than in hyperthyroidism and that after partial thyroidectomy a greater proportion of women between the ages of 40 and 60 have breast or genital cancer than in the average population of the same age[16] Likewise, in laboratory animals, thyroid deficiency sometimes permits a more florid growth of the breast[17]

Benefit from hypophysectomy has so far been largely confined to patients with carcinoma of the breast Most of the reports have come from LUFT and OLIVECRONA and their colleagues in Stockholm[18] and from PEARSON and RAY and their associates at the Sloan-Kettering Institute, New York[12–14] A preliminary report from the Royal Free Hospital, London, has lately appeared[19] and this week we publish details about what is probably the largest series from this country, studied by Mr ATKINS and his colleagues at Guy's Hospital LUFT et al[18] noted objective remissions after hypophysectomy in 22 (54%) out of 41 patients with breast cancer in whom accurate assessment was feasible (that is to say, shrinkage of visible, palpable, or radiological metastases, or increased bone density without progression of the old metastases or appearance of new ones), some of the remaining patients had only temporary symptomatic improvement A similar remission-rate (56%) was achieved in other reported cases, compared with 45% after total adrenalectomy and oophorectomy The duration of remission in LUFT et al 's patients had so far averaged 17 months (only 1 out of 14 was still in remission after 2 years), compared with an average of 9 months after adrenalectomy and oophorectomy They do not, however, feel justified as yet in regarding this difference as conclusive PEARSON et al[13] recorded subjective remissions after hypophysectomy in 21 (51%) out of 41 cases, and the average remission to date was 6 5 months KENNEDY[20] claims objective remissions in 18 (64%) out of 28 patients lasting an average of 7 6 months, with regression of the primary growth, recalcification of the osteolytic lesions, shrinkage of the lymph-nodes and pulmonary and hepatic metastases, and disappearance of skin nodules The Guy's team are the first to compare the results of hypophysectomy and adrenalectomy within their own experience Their findings suggest that the over-

all results of hypophysectomy are superior to those of adrenalectomy, and their patients survived on the average 4 months longer after hypophysectomy than after adrenalectomy, but they emphasise that the differences were not statistically significant. Objective remissions have also followed hypophysectomy in 3 cases of carcinoma of the male breast.[13 18] The results of hypophysectomy in carcinoma of the prostate have been less promising, as have those of adrenalectomy, though temporary objective remissions have been achieved in a few patients in whom endocrine therapy had been ineffective or in whom the condition had relapsed after such treatment.[12 13 18] The operation has been of no benefit in malignant melanoma,[12 13 18 21] hypernephroma,[3] chorioncarcinoma,[12 13 18] seminoma,[22] adrenocortical carcinoma with Cushing's syndrome,[23] carcinoma of the thyroid,[12] and reticulum-cell sarcoma.[12]

There is still no satisfactory means of predicting which patients with breast cancer will respond to adrenalectomy or to hypophysectomy. The histological characters of the tumour are of no help, and there is no correlation between counts of mitotic cells and the response to treatment.[24] There is also no difference between responsive and unresponsive cases in the urinary output of œstrogens and gonadotrophins.[5] Now, however, Dr MERIVALE and his colleagues, on p. 496, report that the ratio of 11-deoxy-17-ketosteroids to 11-oxygenated or 11-hydroxylated 17-ketosteroids was greater than one in the 11 patients who benefited from adrenalectomy or hypophysectomy and less than one in the 4 patients who did not respond (in these 4 cases the pattern of preoperative excretion resembled the postoperative pattern). Estimation of mammatrophin likewise promises to be of value in assessing the hormone-dependence of breast cancer. This substance, which is probably prolactin, is present in the urine of all normal pre-menopausal women during the second half of the menstrual cycle, and in some 38% of normal post-menopausal women. This figure accords with the proportion of human breast cancers which are hormone-dependent—that is, approximately 30%. From a limited series of observations, it seems that a high output of mammatrophin is usually associated with a significant regression of the growth after hypophysectomy, and conversely.[25–27] Studies of the calcium balance may also help when there are osteolytic metastases: the urinary calcium excretion in such cases falls after oophorectomy and rises with the administration of œstrogens,[28 29] and it has been suggested that a rise in urinary calcium excretion in response to a provocative dose of œstrogen, or a fall in excretion induced by cortisone, may indicate that the tumour is hormone dependent and therefore likely to respond to adrenalectomy.[29] LUFT et al.[18] suggest tentatively that in post-menopausal women the chances of benefit from hypophysectomy become progressively less after the menopause and that women over 60 are unlikely to respond; their results also suggest that the response was less satisfactory when the growth had been present for a long time and when there were extensive metastases in the liver and brain. KENNEDY[23] states that the pre-menopausal patient with advanced cancer of the breast who responds to therapeutic castration will probably respond to subsequent hypophysectomy, and that post-menopausal women who respond to œstrogens or androgens will probably also improve after hypophysectomy. And further remissions may result from hypophysectomy in patients who have already undergone oophorectomy and adrenalectomy. PEARSON et al.[12 13] believe that a favourable response to oophorectomy or androgen therapy means that the patient is likely to respond to hypophysectomy, but failure to improve on androgens or œstrogens does not preclude a subsequent response to hypophysectomy.

Some of the disappointments in the early days of hypophysectomy were undoubtedly due to the incomplete removal of the anterior lobe. Better results have been obtained since ZENKER's solution was applied to the sella to necrose remnants of pituitary tissue.[12 18] (RUSSELL's findings[30] indicate that division of the pituitary stalk is followed by selective necrosis of the anterior pituitary and almost total loss of pituitary secretion; but the promise of this simpler procedure does not seem to have been fulfilled.) The development of signs of hypopituitarism serves as a guide to the completeness of hypophysectomy.[14] If the gland has been completely removed, adrenal insufficiency appears within 2 to 3 days if no cortisone is given. The usual replacement therapy is 200–300 mg. cortisone daily, starting on the day before operation, and decreasing gradually after operation to 50 mg. daily by the end of the first week.[13 18] The Guy's team use larger doses (up to 400 mg. daily) for several days before operation, and they implant 300 mg. of deoxycortone acetate after operation. Occasional patients need no maintenance therapy, even though subsequent necropsy has shown that all anterior pituitary tissue was removed. After hypophysectomy the urinary 17-ketosteroid output falls to 0·5–2 mg. per 24 hours, the growth of axillary and pubic hair is retarded, and menstruation ceases; vaginal smears become post-menopausal in character after 1 week and completely atrophic after 2 to 4 weeks. Gonadotrophins usually disappear from the urine after 2 to 3 weeks but occasionally not for 2 to 3 months; but there are no definite menopausal symptoms. Hypothyroidism invariably develops, and the serum level of protein-bound-iodine usually begins to drop after a week and may fall to zero. A prompt fall is good evidence that the hypophysectomy has been complete. The ^{131}I uptake of the thyroid gland may fall equally promptly, but it often stays at about 10% of normal for some months and the thyroid gland may remain palpable for several months. The serum cholesterol level rises slowly by an average of 60 mg. per 100 ml. Clinical myxœdema does not usually appear until 1 to 2 months have elapsed and sometimes not for 4 to 6 months. 60–180 mg. of dried thyroid daily is needed to maintain a euthyroid state. A mild and variable degree of diabetes insipidus develops in

50–60% of patients[19 20] The polyuria can often be controlled by posterior-pituitary snuff (40 mg one to three times daily), sometimes pitressin tannate in oil (5 mg) is needed intramuscularly every second or third day[12 13 20] Other sequelæ of the operation include defects in the visual fields, anosmia, and occasional transient hemiplegia or oculomotor palsy[13 14] The operative mortality is said to be no higher than that of adrenalectomy (PEARSON[12] puts it at not more than 10%), and those who respond well may be able to return to a normal life

Ileitis, Ileostomy, and Cortisone

IT has been suggested that ulcerative colitis is the non-specific outcome of antecedent trauma from a variety of causes[1]—a hypothesis peculiarly difficult to establish, though a statistical approach based on reliable case-histories might prove profitable Meanwhile, the fringes of the central problem of what causes ulcerative colitis are being lightened in several ways, and ileitis provides an example Ten years ago it was common to hear about the dangers of retrograde ileitis following ileostomy The condition had a high mortality, and it was thought that ileitis secondary to the colonic disease spread rapidly up the small intestine after the interference of an ileostomy McCREADY et al[2] held that ileostomy was contraindicated in such circumstances, and, in order to avoid fistula and ileostomy diarrhœa, DENNIS[3] took the precaution of examining the ileum histologically at the site of section and, if he discovered evidence of ileitis, chose a higher level with normal ileum for the ileostomy COUNSELL[4] studied 18 cases of colo-ileitis from a series of 107 treated by primary colectomy or ileostomy and subsequent colectomy, he found that ileitis healed after either ileostomy or primary colectomy, whether the site of the stoma was involved or not BROOKE's results[5] were substantially the same in a late follow-up of 126 patients, excluding a patient with colo-ileitis who died from obstruction, ileitis did not recur in 14, half of whom had been followed for over three years

Why is there this discrepancy between the views of McCREADY et al and DENNIS and the evidence of COUNSELL and BROOKE? COUNSELL's explanation that a confusion had arisen between two conditions is probably correct WARREN and McKITTRICK[6] drew attention to the condition of ileostomy dysfunction, a complication arising soon after operation and made manifest by colic and much loss of fluid from the stoma This condition can arise without previous ileitis, and it is ascribed by some to partial obstruction at the stoma, by others to serositis at and proximal to the ileostomy Here is ileitis secondary to ileostomy, but differing histologically from ileitis secondary to ulcerative colitis Moreover, it can be responsible for perforation, which does not occur in the ileum affected by colo-ileitis, and it may lead to serious trouble and even death from electrolyte depletion It seems reasonable to suppose, therefore, that the ascending ileitis feared by McCREADY et al was due, not to pre-existing ileitis, but to an inefficient stoma, and COUNSELL has observed the condition following colectomy for familial polyposis Certainly "ascending ileitis" is rarely if ever seen today after an ileostomy, and this change coincides with a big fall in the incidence of ileostomy dysfunction—a fall brought about by the simple technique of mucosal eversion, which reduces stomal obstruction[5] and which is also thought by some[7] to eliminate serositis Other things have doubtless contributed to this improvement for example, catheters are no longer left indwelling at the ileostomy after operation, as was the custom ten years ago, and electrolyte imbalance, involving sodium and potassium in such a way as to render small-bowel propulsion less effective, is now better understood In centres where ileostomy is undertaken by experienced surgeons, an undiagnosed Crohn's lesion or enterocolitis, as described by COOKE and BROOKE,[8] is as likely to be the cause of post-ileostomy ileitis as is ileostomy dysfunction though COUNSELL's study of 200 cases at St Mark's Hospital shows that there is still doubt about the existence as a separate entity of the condition which COOKE and BROOKE described

Ileostomy dysfunction caused trouble in 130 of WARREN and McKITTRICK's 210 ileostomy patients, and it was responsible for the death of 7, its elimination is therefore a considerable achievement But no sooner is one bugbear overcome by surgery than another arises That cortisone can induce and prolong remissions in ulcerative colitis has been clearly proved by the Medical Research Council trial[9], but there are some patients who fail to respond and seem to be worse than before COOPER et al[10] noted that preoperative steroid therapy can make the colon friable at operation, and BROOKE[11] has drawn further attention to this hazard Dilatation of the colon, usually in its transverse part, was observed in the pre-cortisone era, and was a sign of impending perforation The same condition seems to develop with greater rapidity and malignancy under the influence of cortisone, and the bowel wall disintegrates to such an extent that it becomes replaced by whatever lies adjacent to it, usually the parietes or small bowel thus raising new and unusual difficulties for the surgeon trying to remove the colon The atony accompanying the dilatation can sometimes be so gross and extensive that colic results from the attempts of the small gut to propel its contents vis-a-tergo through the amotile reaches in front of it This colic and the gross abdominal distension have sometimes induced a mistaken diagnosis of mechanical obstruction by a stricture (in fact, stricture in ulcerative colitis rarely causes obstruction, probably because the fæces are so fluid) Ulcerative colitis is primarily a disease of the mucosa, though often the submucosa is affected as well, but when the colon is dilated, ulceration may be seen histologically to have attacked the muscle coat causing degeneration and destruction of muscle fibres over a wide area Dilatation and disintegration of the colon in cortisone-treated patients is probably due simply to the mechanical effect of a

bowel wall of rotten fabric giving way under the load of its contents, and not to a state of inertia due to potassium loss. Indeed, serum-potassium levels are not consistently low in such patients, and serum values below 3·0 m eq. per litre have been recorded without dilatation. Besides, potassium depletion as seen in steatorrhœa or Crohn's disease causes a small-bowel atony leaving the colon relatively less disturbed, whereas the colonic distension of ulcerative colitis is seldom associated with similar small bowel changes. The fabric seems to rot as ulceration advances unchecked into the muscle, perhaps because cortisone hampers an adequate inflammatory response in this layer. There is substance, therefore, in the suggestion[11] that the degree or depth of damage to the bowel wall should be assessed radiologically before corticoids are given. If pockets are seen outside the bowel lumen or if what has been called "pseudohaustration" is apparent, these should be taken as danger signals, since ulceration has then certainly reached the submissive muscle layer.

Annotations

POLIOMYELITIS VACCINE

IT is almost two years since poliomyelitis vaccine was licensed for manufacture in the United States, and since then manufacturers, doctors, and the public have had their share of anxiety. But there is little cause for alarm in last week's news that distribution of the latest batch of the British vaccine must be delayed until a colour change in certain vials of vaccine, in store since mid-November, has been investigated. As things have turned out, it would of course have been better to defer the announcement from the Ministry of Health about the distribution of the vaccine until it had passed its final scrutiny.

The vaccine contains a colour indicator of pH which is a useful guide to the metabolic state of the tissue culture during growth of the virus. A change in pH during storage (indicated by the vaccine changing from pink to yellow) might be due to bacterial contamination which had escaped detection earlier in the manufacturing process. This has not apparently been a serious complication in the past. The cause of the pH change is now being investigated. The delay thus involved, disappointing though it is, illustrates the enormous care that is being taken to make the vaccine as safe and effective as possible.

There are clearly many difficulties still to be overcome in producing poliomyelitis vaccine, and at a recent meeting of the New York Academy of Sciences Dr. J. E. Smadel reported that, even after two doses of present-day commercial vaccine, antibodies sometimes failed to appear in children with no pre-existing antibodies to any of the three poliomyelitis viruses. Smadel thought that this might be due to the current practice of ensuring safety by repeated filtration, and consequent loss of antigenicity. From the start, the fundamental trouble with formalinised poliomyelitis vaccine has been the narrow margin between a vaccine which has not been sufficiently inactivated and contains live virus and a vaccine which has been over-formalinised and is not a sufficiently potent antigen. The result has been that different batches of vaccine supposedly made by the same methods, have varied greatly in their behaviour. It may have been unwise to invest so much in formalinised vaccine, and the possibilities of inactivating the virus in other ways should still be investigated.

DOCTORS AND UNEMPLOYMENT BENEFIT

A FEW years ago it would have been unthinkable that doctors should draw unemployment benefit, but some of them are doing so today. Most of these unemployed doctors are no more than temporarily out of work, and they are usually young men who have had difficulty in getting a house job, though there are rare instances where a hard-pressed registrar has asked for help. As we have earlier observed,[1] circumstances can arise whereby weeks and even months may be lost by a newly qualified man between his first and second preregistration jobs; and no longer can this period be filled profitably by a locum tenancy in general practice. During one appointment of six months few housemen can save much against a rainy day and some of them naturally turn to the State for support during the temporary lean period. Indeed, they have already contributed money as an insurance against this very predicament.

Another influence, perhaps more forceful than the preregistration year, is the climate of the times. As taxation eats into personal income and contributions to National Insurance make further inroads, it seems hard to reproach professional men for claiming their due from the State when they are in difficulties. On the other hand, it was no doubt the prevalence of the "claim-what-you-can" attitude, rather than real hardship, which led a newly registered doctor, who had a month to wait before his next appointment, to claim unemployment benefit for that period, with allowances for his two children, though his wife, also a doctor, would be continuing to earn. He even wondered whether he might successfully apply for National Assistance because the mortgage rates on his house were high. He had no doubts about getting unemployment benefit *for the* whole period, since it seemed unlikely that the labour exchange would be able to find him a job in his "trade" which he would in any case have to refuse because of the job to which he had already been appointed.

Such a story may shock doctors of an older generation; nevertheless, we hope they will not support the action of the dean of one medical school who (we understand) refuses testimonials to any man who has drawn unemployment benefit. Doctors have all the rights of other citizens, including the right to behave how they wish in such matters; and there are undoubtedly instances of genuine need.

FRACTURE OF THE ODONTOID PROCESS

CONSIDERABLE violence is usually necessary to fracture the odontoid process of the axis, and the injury is now most commonly seen after road accidents. The mechanism of the fracture has aroused much interest. Undoubtedly the sudden movement of the head upon the upper cervical spine imposes an immense strain upon the odontoid, which is probably damaged by a combination of traction and leverage through the alar ligaments. Wusthoff[2] has emphasised the importance of the transverse ligament in the production of *odontoid fractures*, but in certain lesions the anterior arch of the atlas must be of equal importance. Patients with this injury usually have severe pain, often radiating to the occipital region. The head is sometimes rotated, making X-ray examination difficult, and the patient may support it with his hands. Paraplegia is present from the start in about 10% of the patients who survive the immediate injury; but the proportion may really be *much* higher, since severe cord damage at this level is always fatal.

Up to the age of 6 years the primary centre of ossification of the odontoid is separated from the centre for the body of the bone by a cartilage plate. Blockey and Purser[3] have shown that in the young child the injury is similar to an epiphyseal separation, and is normally followed by firm bony union In the adult, however, bony union is uncommon and occasionally a late paraplegia follows Although this complication usually appears within the first year after injury, it has been reported as long as 28 years later If the paraplegia is due to instability, then early spinal fusion might be expected to lessen its incidence

---

The early treatment of the fracture demands traction, and the skull calliper is undoubtedly the best method Careful positioning may assist reduction if the fragment is displaced, and by flexing or extending the head accurate alignment of the fragments is possible Even for the undisplaced fracture, light traction affords a convenient method of immobilisation If the fracture can be maintained in a good position for 3 months it may well unite, although even then fibrous union is not uncommon Such a result is compatible with good function and freedom from pain, but nervous complications may ensue

DEODORANTS AND THE SKIN

DEODORANTS are amongst the most commonly used cosmetic preparations, and they are marketed in the form of liquids, creams, pastes, powders, or sticks They are of two types substances which destroy or obscure the odour and those which, being astringents, diminish the flow of perspiration Most preparations contain a proportion of each type The first group includes such substances as sodium perborate, zinc peroxide, hexamethylenetetramine, chloramine-T, chlorothymol, oxyquinoline sulphate, perfumes, and essential oils Among the astringents, which act by precipitating skin proteins, thus blocking the ostia of the sweat-ducts, are formaldehyde, aluminium chloride, sulphate, and phenolsulphonate, zinc salicylate and phenolsulphate, tannic acid, and the tannates Formaldehyde is now rarely used, since, in an effective strength, it is a primary irritant The very efficient aluminium salts are often used in liquid preparations, they are also primary irritants and sensitisers, but their irritant effect can be eliminated by buffering the solution with urea

Dermatitis caused by deodorants is usually confined to the axillæ, where it takes the form either of a sharply limited erythematous vesicular eruption or a folliculitis Patch testing will confirm the cause of the eruption and distinguish it from dress shield dermatitis Rubin et al [1] have lately described a new type of local skin reaction in the axilla after the use of certain deodorants They record 4 cases in detail and they mention that they have already seen 11 other similarly affected patients Of the first 4 patients, 3 had used stick deodorants and 1 a liquid preparation After periods varying from two days to a month, irritation and an eruption suddenly appeared in the axillæ The rash consisted of dusky reddish-brown discrete papules 1–4 mm in diameter They were closely set in the domes of the axillæ and more sparsely placed at the periphery The lesions looked semitranslucent but no fluid could be extracted by puncture An "apple jelly" appearance was produced by diascopy Treatment with superficial X rays and topical hydrocortisone had little effect except for a slight yellowing in colour and moderate scaling

Histological sections from a biopsy specimen of an axillary papule from each patient showed a tuberculoid granuloma situated in the corium It consisted of epithelioid cells and Langhans giant cells surrounded by lymphocytes in typical tuberculoid pattern Necrosis was absent The sharp delineation of tubercles as seen in sarcoidosis was lacking The infiltrate lay along the course of the blood vessels Foreign bodies could not be detected by polaroscopic examination The stick deodorant used by 3 patients contained apart from the commonly used ingredients, sodium zirconium lactate, but this substance could not be demonstrated spectrographically in the biopsy specimen from 1 patient The lotion used by the 4th patient contained chlorhydroxyaluminium sulphate but no zirconium

Rubin et al say they cannot be certain of the cause of this granulomatous eruption They mention a linear distribution of lesions and they are now investigating the possible rôle of razor abrasions They do not say whether any or all of their patients wore dress shields and if so whether sensitivity to them had been excluded In any case, this type of granulomatous reaction is unusual and further observation is needed

OPEN HEALING OF TUBERCULOUS CAVITIES

EVEN after long periods of chemotherapy for chronic pulmonary tuberculosis, tubercle bacilli can often be cultured from the walls of cavities in resected specimens by simple [1] or elaborate [2] methods, and we have referred [3] to some of the changes in the lesions after chemotherapy Perhaps the most important, and certainly one of the most interesting, aspects of chronic tuberculosis is open cavity healing in the lungs—a type of healing recognised as very rare before the days of chemotherapy [4] Auerbach [5] pointed out that open cavity healing was commoner after chemotherapy (his examples referred to treatment with streptomycin plus *p*-aminosalicylic acid), that the cavity walls were thinner the sooner treatment was begun, and that the draining bronchus was re epithelialised Thomson [6] showed that the incidence of open cavity healing had risen remarkably with the introduction of isoniazid, and that two-thirds of such cavities became completely healed, though areas of minute ulceration were still present in the other third No tubercle bacilli could be seen in sections of the walls In resected lesions including more than cavities, Allen [7] found that over 10% were positive on culture and 10% on smear In 10% of Allen's patients the disease became active again after chemotherapy, even after conversion (by a combination of all three drugs) of gastric washings and sputum, and Allen recommends surgery after three or four months' chemotherapy, especially for thick-walled cavities, caseous masses over 2 cm in diameter, and bronchial stenosis or bronchiectasis

A careful clinical, pathological, and bacteriological study of persistent thin-walled cavities has lately been reported by Keers et al [8] From the first 10 out of 14 patients who had such cavities and whose sputum had been converted by a few months' chemotherapy of various combinations, the lesions were resected after a further four months' or more chemotherapy The walls of the cavities were sometimes uniformly smooth and sometimes trabeculated, and others showed large or small granular areas with or without caseous material or thin pus Histologically, the picture was just as variable, and there was evidence of activity even in cavities which looked smooth and shiny None of the cavities showed complete epithelialisation, though in several of them epithelium had grown from the junction between cavity and bronchus for 2 or 3 cm along the cavity wall Elsewhere a smooth fibrous wall sometimes seemed to have a surface layer of flattened fibroblasts Tubercle bacilli were identified (4 times by culture and 4 times by smear) in 5 out of 9 cavities from 8 patients Altogether 11 positive cultures were obtained from 3 patients (4 cavities) and of these, three strains from 1 patient were found to be resistant (two completely to P A S and partially to streptomycin, one partially to streptomycin), but all were sensitive to isoniazid and all were sensitive to a combination of the three drugs These results suggest that the common finding in America [9] of organisms sensitive to isoniazid after treatment with streptomycin and isoniazid is due not so much to the antagonism to streptomycin of the desoxyribonucleic acid in the cavity contents as to the low dose of streptomycin (1 g every third day), which means that the streptomycin and isoniazid cannot exert their mutual protection Keers and his colleagues combine their observations to show that only one of the cavities in their series could be described as "healed" and even then there was active tuberculosis elsewhere in the lungs They have 4 other cases with similar lesions under chemotherapy, and they point out that, while resection gives valuable information, more conclusive evidence can come only from long clinical follow up of such patients treated by chemotherapy alone

[8] Keers R Y Riddell P W Reid L *Tubercle Lond* 1956 37 401

Stewart et al [10] investigated bacteriologically and histologically 71 resected specimens of lung tissue, including 50 pulmonary cavities 11 were described as having smooth shiny walls, and no tubercle bacilli were cultured from 9 of them The 2 patients from whom bacilli were recovered had had less than twelve months' effective chemotherapy before operation The most important conclusion of this detailed investigation was that drug resistance and the duration of effective chemotherapy were the main factors affecting healing Viable bacilli were obtained from 96% of caseous foci and 95% of cavities in these patients in whom drug-resistant bacilli had been demonstrated in the sputum at any time, but the corresponding figures for the drug-sensitive group were 9% and 17% Only 2% of the lesions from patients who had had twelve to eighteen months' treatment were positive Stewart et al claim that chemotherapy can sterilise tuberculous lesions and that open healing of cavities can be achieved provided that only those combinations of drugs known to prevent the emergence of resistant bacilli are used and that treatment is continued for at least twelve months Even longer treatment may give greater chances of healing, and two years would not now be considered out of the ordinary Stewart et al suggest that a long period of chemotherapy may often prove a satisfactory alternative to surgical treatment This possibility is attractive, but some may feel that the evidence does not yet justify looking at ring shadows in the radiograph with anything but disfavour

The introduction of isoniazid is one of the reasons why it has been possible to collect so large a series of persistent thin walled cavities as Keers et al [8] have done The fact that isoniazid was part of the treatment of 11 of their 14 patients and in 12 of them radio opaque material entered 13 cavities, supports Thomson's finding that open healing of cavities is commonest after isoniazid Further support for this view comes from a study of urinary tuberculosis with cystitis, Borthwick [11] showed that the three combinations of streptomycin, isoniazid, and P A S all gave good results, but streptomycin plus P A S was more likely to lead to severe bladder contracture, isoniazid plus P A S was followed by practically no bladder contracture, and streptomycin plus isoniazid came in between the two in this respect Thus, if the aim is to produce fibrosis in any tuberculous lesion, streptomycin especially with P A S may be the best treatment (though the evidence that streptomycin promotes fibrosis is by no means complete) and to avoid fibrosis and promote as much resolution as possible, isoniazid plus P A S may be the choice And it may turn out that the same principle applies to lung cavities according to the density of their walls and the possibilities of drainage for thick-walled cavities which would never resolve but could be sealed off, streptomycin plus P A S may be best, for thin-walled cavities, to get as much drainage and then resolution as possible, a combination including isoniazid may be most effective At present however the choice of drugs cannot be based on these possibilities for one thing, they are little more than speculation and for another, different types of lesion are often found in the same patient

OFFICIAL OR PROPRIETARY?

FEW people have welcomed the Government's action in multiplying the prescription charges [1] A less unpopular line of attack on the National Health Service drug bill has been the effort to dissuade doctors from prescribing proprietary drugs, which are often (though not always [2]) more expensive than similar drugs supplied under the official title Many doctors agree in principle, but feel that certain proprietary preparations have an advantage in practice over the corresponding official preparations even though their content is apparently identical This view is supported by the findings of Bagnall and Stock,[3] who subjected 343 samples of barbiturate tablets to tests specified in the *British Pharmacopœia* The two most important of these are the disintegration test, which measures the capacity of the tablet to break up in the stomach, and the uniformity test, which measures the weight of the drug in the tablet [4] Thus the uniformity test determines whether the patient is receiving the intended dose, and the disintegration test is a guide to whether or not the drug will be absorbed Of the 343 samples, which included drugs marketed under both official and proprietary titles, 79 failed to conform to pharmacopœial standards, most failures were in the disintegration test 11 of the samples were proprietary mixtures which need not have complied with the *B.P.* requirements, but in fact all did so

Bagnall and Stock point to the startling difference in quality between the tablets of different manufacturers No fault was found in the 83 samples which represented four firms, but of the 67 samples representing two other firms no fewer than 42 were below standard The age of a tablet influences its disintegration, but 5 year old tablets from some firms behaved better than 5 week-old tablets made by others, and even 18 year old tablets made by one firm still fulfilled the *B P* requirement There were some surprising variations in the dose of active material among tablets of a given batch (up to 25%), and $^1/_2$ grain tablets were found in a tin labelled $1^1/_2$ grains.

Some drug manufacturers, on both sides of the Atlantic, spend a lot of money on research which is important even indispensable Other firms with lower standards make no such contribution, and they can thus undersell their competitors, but their products may be inferior Though a higher price does not guarantee a better product, a lower price often means a poorer one, even though both preparations carry the same pharmacopœial name If a doctor's experience has convinced him that certain proprietary medicines are better than those which may be supplied as official equivalents it is clearly his duty to reject what he considers an inferior substitute Until stricter control has ensured that the *B.P.* standards are maintained and that preparations which do not satisfy them are rarely if ever supplied, the Government cannot assure prescribers that official preparations are invariably as effective as the corresponding proprietaries

PAPWORTH'S RESULTS

Rehabilitation of the Tuberculous under the Ministry of Labour Training Scheme 1948-55

R R TRAIL
C B E, M C, M.D Aberd, F R C P
MEDICAL DIRECTOR, PAPWORTH AND ENHAM-ALAMEIN VILLAGE CENTRES

THE main effort made by the community on behalf of the disabled worker and his family takes the form of financial grants The idea of Papworth, first propounded by Varrier-Jones forty years ago, has been different—namely, to provide the tuberculous with work and wages under sheltered conditions

Up to the outbreak of the late war the hospital and industries at Papworth developed steadily, and they were able to play a part in the industrial war effort But, when more and more Servicemen required rehabilitation, there was obviously need for schemes of training that could be started early in treatment, while the men were still receiving their Service pay, and which should be directed to fitting them for normal civilian employment as soon as they were restored to health

The introduction of the National Health Act of 1948 opened the way for Papworth to extend this side of its work, and a coördinated scheme was started with the Ministry of Labour, who recognised Papworth and Enham-Alamein as training centres

The Scheme

Under this scheme patients can come to Papworth or Enham-Alamein as soon as they are fit for three hours work daily, and increase gradually to six hours daily No hard and fast rules are made about the length of residence, each patient is considered on his needs and training may last as long as three years The object is to place him in self-supporting work as soon as possible, though the aim must always be to see him trained sufficiently to command trade-union membership

A positive sputum is no bar to admission indeed it is one of the best reasons for admission because chemotherapy can be safely continued during training Papworth, because it is also a sanatorium, can offer earlier training than other centres which accept also men with other forms of disability

Selection

After perusal of radiographs and reports, patients (both men and women) are accepted on the assurance that the local chest physician thinks them fit to start three hours' work daily at once A few are interviewed first, but most of them arrive virtually unchecked and with little idea of their future programme

Some of our trainees were "old lags" whom chest physicians hoped to get rid of, some had been promised a house at once, some were youngsters whose careers had not yet started and who were eager to train, but most were ordinary folk whose lives had been upset by tuberculosis and who hoped for a fresh start in life

The first three months is regarded as a probationary period during which the trainee, the chief medical officer, and the industrial manager can assess the future The patient may not, in fact, be fit enough to start work, he may be uncooperative or unsuitable for training, or he may not like what he finds and may prefer to go home In view of our method of acceptance this trial period is a valuable safeguard

Seven Years' Results

From 1948 to 1955 926 men and women were accepted for training at our two centres, Papworth and Enham-Alamein Of these, 63 (7%) did not complete the probationary period Of the remaining 863, 211 were still in training at the time of the review Of the 652 who had terminated training 162 (19%) had been "colonised"—i e, they had reached a standard of industrial proficiency acceptable to the appropriate trade union and had been offered work at Papworth A further 60 trainees had completed training to the satisfaction of the authorities, but had decided not to remain at Papworth Many had been offered employment nearer their homes

Reasons for Leaving Prematurely

409 (47%) ended their training prematurely for the following reasons

To take other work	120
To a different training course	23
Marriage	15
Other domestic troubles	61
Unsettled (own request)	66
Discharged (unsuitable)	47
Unfit (requiring treatment)	70
Died	7

It will be seen that a third of this group left either to take other work or to change on to a different training scheme Obviously it is not possible to provide more than a few trades at one centre, and transfers to other centres were arranged by the authorities if the man seemed a responsible person, medically fit, and likely to continue training These figures show that 365 (56%) of those who left the scheme had either completed training (34%) or found work elsewhere, they form the obvious successes

Those who left to take other work usually had found more suitable or more congenial employment nearer home Many of them had come to Papworth because they could not get such work, and their departure was a satisfactory sign of increasing skill and increased confidence in themselves

The "domestic" reasons for leaving cover the sad difficulties which accompany long separation it is wisest to recognise the inevitable, and if the man returns home the disruption of a family may often be avoided One effort at rehabilitation is of small significance in a man's life, compared to the permanent tragedy of a broken marriage In considering requests for early discharges and extra leave the training centre must always be prepared to compromise

The 66 who left of their own accord because they were 'unsettled," and the 47 who were discharged as unsuitable together make 13% of the entry This percentage is comparable to the self discharge rate of many sanatoria Most of them had not been on the training scheme for six months and were still only doing three hours work daily It may be that an adequate explanation of their progress had not been given to them, or that they were temperamentally unsuited to a long apprenticeship Whatever the cause, in this group the training was unsatisfactory, though they were assessed as suitable during their probation

Length of Training

Of the 402 who left, 278 had been training for more than six months, and 265 were working five hours or more a day The following figures show the time spent at each grade of training by those who completed the training (A) and those who did not (B)

	(A)	(B)
3 hours' work daily	25 weeks	23 weeks
5 hours' work daily	31 weeks	23 weeks
6 hours' work daily	41 weeks	11 weeks

The real difficulty thus lay in the long period on six hours daily which was needed to reach an adequate industrial standard Obviously training cannot be really intensive until the man is working almost a full day Those who liked the work stayed the full time those who were impatient, or needed better money left as soon as they felt confident of their *medical* stability, or sought a livelihood elsewhere regardless of the risk to their health

When considering the length of the training it must be remembered that most of the trainees were starting industrial work at a time when they would otherwise be doing grade work in a sanatorium The first six months, therefore, is one of careful medical control The training is recognised by the trade unions as apprenticeship in a trade the usual apprenticeship in ordinary industry is three, five, or more years, and a shorter period is accepted for medical trainees only because they are older men and can progress to responsibility more quickly

On the average, trainees spent six months on three hours work only, to allow adequate rest during the afternoons This is essentially a period of medical rehabilitation The period on five and six hours' work is industrial training Usually the trainees are ready for colonisation during the second year, but 68 severely disabled patients took over twenty-four months

Absenteeism

We have defined absenteeism as any absence from work of less than four consecutive weeks, whatever the cause Longer periods of absence are considered as relapse This criterion is stricter than that used by the Ministry of Labour for fit people in normal industry, and yet, as the following figures show, our results are as good

Daily work span	Absenteeism during training	
	Subsequently colonised	Left before colonising
	(total 162) (%)	(total 469) (%)
3 hours	4 5	6 8
5 hours	5 2	6 7
6 hours	4 5	6 7

In both groups the absentee rate is remarkably constant, but it is lower among those who later colonised The records of 50 settlers who have worked in the colony for upwards of thirty years showed the same absentee-rate of 4 5% The rate throughout industry for 1953 was 4 2% Judged by these figures, the worker who has had tuberculosis is reliable and industrious, and does not have an unduly high absentee-rate There is so much at stake, and his chances of employment are relatively so much less, that this is to be expected

Relapse

Any absence from work for more than four consecutive weeks was counted as a relapse This obviously includes many cases in which the illness was unrelated to tuberculosis—e g, one fractured femur due to a motor accident

Of the 631 trainees 149 had a " relapse " during training, but 86 were able to resume training after treatment, and 24 of these did in fact later colonise These figures were for 1948–55, and it is uncertain what effect long term chemotherapy will have on relapse rates

The fact that so many of those who relapsed were able to go on with their training shows the value of a training centre where patients can if need arises be admitted into hospital, and after treatment resume training without losing the benefit of their previous experience Only under such conditions can training be started early in a disease whose prognosis is so fickle This arrangement gives the maximum of security and opportunity to the marginal cases in which the patient would otherwise have no hope of regaining his economic independence within a reasonable time No private employer could be expected to carry such a risk no standard scheme of training for a fixed period on a full day's work could accept these patients in the early stages without excessive risk

Sputum-positive Patients

Village settlements have been criticised for abandoning their original principles in order to achieve economic success Most of the patients admitted nowadays, it is said, are so fit that rehabilitation is unnecessary There are two replies to this assertion

Firstly, most of the trainees have come to Papworth because they were unable to find employment near home This may have been due to their medical condition or to natural reluctance and anxiety about resuming work after a long period of treatment in which the need for rest was so constantly emphasised In either case training for a trade was valuable because it produced a feeling of confidence and ability as well as giving the man a skill with which to earn his living

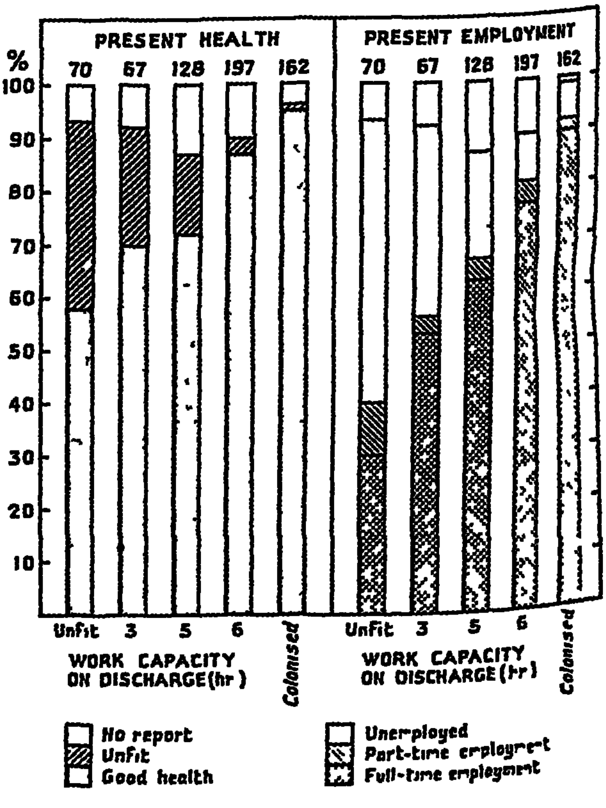
Secondly, 214 (25%) of those accepted for training had a positive sputum on admission, and they have been included in all the results discussed During their training chemotherapy and/or collapse therapy was started in an attempt to convert the sputum One of the earliest trials of ambulant chemotherapy reported in this country was done on these trainee patients

In 137 patients the sputum was converted during training, and has remained negative during the follow up period 77 patients remained sputum-positive throughout, but 15 of these were not considered suitable for any treatment

Follow-up

Of the trainees who left the scheme either by colonisation or to return home 91% have been traced and have provided information of their present status, health, and employment (see chart) 88% remain under regular medical supervision

The term " good health " implies that the man feels well, is living a reasonably normal active life, and has



been told by his doctor that he is fit for work Those who persisted with their training show a better health record and a better employment state

Of those who left while only doing three hours' work, 76% are now considered fit, but only 51% are in full-time work. Of those who remained to a six-hour grade 87% are reported fit and 77% are fully employed Of the colonists 90% are in full work at union rates of pay

Only 5% have managed to find part-time jobs To advise a patient to take light unskilled part-time well-paid work is as unrealistic today, even in a period of full employment, as it was at the birth of Papworth

Discussion

The nature of tuberculosis and the rôle of the settlements has changed since they were founded Today treatment can aim at recovery and subsequent employment For many patients their old job is open others have no job or an unsatisfactory one A long illness offers them opportunity to train for a better job

Rehabilitation in tuberculosis should start at the time of admission to hospital and should continue until the man is satisfactorily placed in employment It should be more than a diversion or occupational therapy · it should be practical training in a chosen trade The trainee deserves the same individual attention as a patient his rehabilitation must be planned in the same way as his treatment As early as possible he should start a few hours' work in a factory, again doing a normal man's job and producing sensible saleable articles

Time must not be wasted with purposeless grade work and futile occupation to pass the time Time is precious to a young man, and doctors must not regard as trivial the valuable months of other people's lives Rising morale due to clinical recovery must be harnessed as the driving force of full and final economic recovery

If this is true in tuberculosis it is also true of many other diseases which leave a disability and prevent return to previous employment In many of them treatment and training could proceed together, and the time could be used to good purpose instead of being a burden on the mind Often the period of illness can be used to train a man for a job within his future capacity and ensure his continued economic independence

Papworth has changed its routine to keep abreast of requirements the Ministry of Labour scheme is built on that experience and its results are good

MEDICAL INSURANCE AGENCY

THE Medical Insurance Agency, which this month reaches the half-century mark, was puny in its earliest years and none too robust in those that followed, but now, in full maturity, it is massive and sound, vindicating the judgment of the two men who had the idea of bringing it into being These two were Dawson Williams, editor of the *British Medical Journal,* and Squire Sprigge, editor of *The Lancet* The story goes that, meeting for luncheon, they fell to talking of the large commission which an agent had received for a life assurance policy taken out by a doctor, and this led them to agree that an organisation should be set up to secure the best possible terms for each doctor, paying rebates to the insured persons and turning over the surplus to medical charities

The first meeting of the Agency (known until 1913 as the Medical Insurance Committee) was held on March 7, 1907, under the chairmanship of Radcliffe Crocker, treasurer of the British Medical Association (Throughout its fifty years the Agency has been powerfully supported by the association, but has always operated independently) In 1909, on Crocker's death, G E Haslip took over the chairmanship, approaching his task with lively vigour In its first years the Agency had been concerned chiefly with insurance against risks under the Workmen's Compensation Act of 1906, but in 1909 motor-car business was undertaken and proved immediately successful, and in the next few years life assurance increased apace After Haslip died in 1924, Sir Humphry Rolleston was appointed chairman, holding office until he resigned in 1942, when he was succeeded by Sir Robert Hutchison When he, in turn, resigned in 1947, Dr James Fenton was elected, and he continues in office

In the early years after the late war, the Agency arranged many loans for the purchase of practices When the National Health Service Act came into force in 1948, these purchases stopped, but the gap was largely filled by loans for housing Since the end of the war the business transacted by the Agency has grown impressively Whereas in 1946 premiums collected amounted to £450,000, in 1956 they totalled over £2 million, and whereas in 1946 £5000 was distributed to medical charities, by 1954 the figure had increased to £24,500 Much of this success can be ascribed to two men—Dr Henry Robinson, the hon secretary since 1938, and Mr A N Dixon, the general manager After his appointment, Dr Robinson took a leading part in a thorough overhaul of the Agency's affairs, and it was decided to secure a trained insurance expert as manager Mr Dixon's appointment (he was one of 550 candidates) resulted

The Agency's reputation stands deservedly high In seeking insurance through it a doctor serves well not only himself and his own family but others less fortunately placed It is not often that two such diverse purposes can be so surely achieved by a single step

---

Medicine and the Law

Subject to Correction

A COLLIERY worker, whose right eye had been injured in an accident at work in 1936, suffered a further injury at work, this time to his left eye, in March, 1955, as a result of which he was rendered almost totally blind He claimed disablement benefit under the National Insurance (Industrial Injuries) Act, 1946, which requires, where a worker has suffered injury to a " paired organ," that the medical board must assess the extent of disablement in accordance with regulation 2(5) of the National Insurance (Industrial Injuries) (Benefit) Regulations, 1948 Two medical boards made provisional awards assessing the extent of the disablement at 100%, but a third board, in March, 1955, made no award The worker thereupon appealed to the Medical Appeal Tribunal at Newcastle-upon-Tyne, which, on June 13, 1956, made an award assessing the disablement at 20% That award showed clearly that the tribunal had overlooked the requirements of regulation 2(5)

The worker applied *ex parte* to the Divisional Court of the Queen's Bench Division, asking *inter alia* for an order of *certiorari* to quash the tribunal's decision on the ground that there was a manifest error of law on the face of that decision The Divisional Court dismissed the application, but the Court of Appeal gave leave to appeal When the appeal came on for hearing, counsel for the Ministry of Pensions and National Insurance and for the tribunal conceded that there was such an error and did not oppose the application for *certiorari*, he also stated that the tribunal would redetermine the claim and make a new assessment, but the Court took time to consider whether it had jurisdiction to make the order asked for, in view of the fact that section 36(3) of the Act of 1946 provides that " any decision of a claim or question . shall be final "

Lord Justice DENNING, reading his reserved judgment, said that it was clear that the tribunal had gone wrong in law, and its error appeared on the face of the record The point then arose as to the effect of section 36(3) of the Act of 1946, which said that "any decision of a claim or question shall be final" Did those words preclude the Court of Queen's Bench from issuing an order of *certiorari* to bring up and quash the decision? On looking again into the old books his Lordship found it very well settled that the remedy by *certiorari* was never to be taken away by any statute except by clear and explicit words The word "final" was not enough, it meant only "without appeal" It made the decision final on the facts but not on the law

The value of this ancient writ was well shown by the present case, for it was only by reason of it that a workman blinded at work had obtained the industrial-insurance benefit to which he was by law entitled, as now acknowledged on all hands The order must issue to quash the tribunal's decision The tribunal would consider the claim afresh and no doubt come to a right decision on it

Lord Justice ROMER, concurring, said that it would have been deplorable if the Court had been constrained to hold that the decision of a medical appeal tribunal, however obviously wrong in law, was immune from review by Her Majesty's Courts The tribunals did their work conscientiously and efficiently, but in the nature of things they were bound to go wrong from time to time in matters of law Their members consisted in the main of people who had devoted their lives to activities far removed from the study and practice of the law and neither by *training nor experience could they be expected to have* that knowledge of the principles of construction which was so necessary for the proper understanding and application of the statutes and regulations which often came before them

Lord Justice PARKER delivered a concurring judgment The appeal was allowed

Regina *v* Medical Appeal Tribunal *Ex Parte* Gilmore *Court of Appeal* (Denning Romer and Parker *L JJ*) Feb 24 1957 David Turner Samuels (Gaster & Turner for I E Geffen, Durham) Rodger Winn (solicitors Ministry of Pensions and National Insurance)

Barrister at-Law

Difference in Technique not Negligence

On Aug 19 and 23, 1954, the plaintiff, then aged 54, a voluntary patient in a mental hospital suffering from an anxiety state was given electro convulsive therapy (E C T) During the course of the treatment on Aug 23, he sustained bilateral "stove in" fractures of the acetabula In accordance with his normal practice the doctor treating the plaintiff had given the E C T "unmodified"—i e, without using relaxant drugs and without applying any form of restraint other than to support the plaintiff's chin and to hold his shoulders The treatment was given while the plaintiff was lying on a couch and the precautions taken were the use of a gag and the presence of nurses on each side of the couch in case he fell off The plaintiff sued the hospital management committee for damages for his injuries, his case was, in effect, that they were negligent (1) in failing to warn him of the risks involved so that he had had no chance of deciding whether or not to take those risks, (2) in failing to use any relaxant and/or anesthetic drug, and (3) since they had not used any relaxant drug, in failing to provide at least some form of control beyond that which was given The defendants denied negligence

The doctor who had been in charge of the plaintiff gave evidence to the effect that he was normally opposed to the use of relaxant drugs as he considered that there was, with their use a risk of mortality while he considered the risk of fracture with unmodified E C T to be minimal, he said that he only gave relaxants in selected cases where the risk of unmodified E C T would be greater than usual, and that there was no special reason why the plaintiff should have been given a relaxant drug Witnesses called by either side gave evidence as to the different techniques which they adopted in giving E C T some used restraining sheets, some relaxant drugs, some manual restraint, but all agreed that there was a firm body of opinion which was opposed to the use of relaxant drugs as a matter of routine although one witness, called by the plaintiff, preferred to accept the risk of relaxant and eliminate the risk of fracture The witness called for the plaintiff considered that, if a relaxant drug were not given, it would be unwise to give E C T without some form of manual restraint, the defendants' evidence was that they used to provide manual control but had not done so since 1951, that it was their view that the less restraint there was, the less the risk of fracture, and that that view was borne out by their experience Two of the witnesses treated their patients in an ordinary hospital bed covered by the bedclothes, and one of those agreed that the mattress and bedclothes to a certain extent absorbed and restrained the convulsive movements of the patient As to warning patients of the risk, it appeared that it was the practice of defendants' doctor to say little about the treatment and to wait for the patients to ask questions, he did not think it desirable to say anything about risks unless asked, if asked, he said that there was a very slight risk The plaintiff's witness thought that it was not right not to warn a patient of the risk of fracture It also appeared from the evidence that the nature of the plaintiff's injury was exceptional

Mr Justice MCNAIR, summing up to the jury, said that they must bear in mind the enormous benefits which E C T conferred upon patients suffering from certain forms of mental illness The use of E C T was progressive and they might well think that even today there was no standard settled technique with which all competent doctors would agree on all points Where there was a difference of opinion among medical men, a doctor was not negligent if he acted in accordance with a practice accepted by a competent body of medical men skilled in that particular art In other words a doctor who acted in accordance with a particular practice was not negligent merely because there was a body of opinion which took a different view, but at the same time that did not mean that a doctor could obstinately and pig headedly carry on with some old technique if it was proved contrary to substantially the whole body of medical opinion It was not for the jury to decide which of two practices was the better

The allegation that the failure to warn was negligent raised two questions First, did good medical practice require that a warning should be given to a patient before receiving E C T? The jury might well think that a doctor, dealing with a mentally sick man and having a strong belief that his patient s only hope was E C T should not be criticised if he did not stress the dangers which he believed to be minimal If they thought that a warning should have been given, then the second question was what difference would it have made? The plaintiff, the only person who could have answered had not been asked that question, and unless they were satisfied that he would not have taken the treatment if he had been warned they might well think that there was nothing in that point As to the other allegations of negligence it was for the jury to decide on the evidence whether or not the defendants, in failing to take the action which the plaintiff alleged should have been taken had fallen below the standard of practice recognised by a reasonably competent body of medical opinion The evidence as to the use of restraints showed that there were different ways of carrying out the treatment but it was not right to take that as condemning the practice adopted by the defendants

The jury found for the defendants, and his Lordship entered judgment for the defendants, with costs

A TUBERCULIN SURVEY OF 1285 ADULTS WITH SPECIAL REFERENCE TO THE ELDERLY

D GIANNINI
L R C P E
REGISTRAR

R S SLOAN
M B Glasg, D P H
LATE JUNIOR HOSPITAL MEDICAL OFFICER

RUCHILL HOSPITAL, GLASGOW

TUBERCULIN testing in the course of routine clinical work at this hospital has disclosed a surprisingly high number of non-reactors among older people For this reason a systematic survey of adults was made

Material

Tuberculin tests were made on persons aged more than 15 It was impossible to survey the general population, but it was thought that a survey of patients admitted to hospitals serving the northern area of Glasgow would be sufficiently representative Certain patients were excluded

(1) Those with, or suspected of having, tuberculosis

(2) Those with conditions which affect tuberculin sensitivity—e.g, acute illnesses, illnesses producing grave debility, collagen diseases, and reticuloses

(3) Those receiving treatment which might affect tuberculin sensitivity—e g, cortisone and corticotrophin

Methods

Tuberculin sensitivity was tested for by the injection of Old Tuberculin (Evans) into the skin of the volar aspect of the forearm The initial dose was 10 T U (0 1 ml of 1/1000 dilution O T) Care was taken to exclude technical errors—e g, from a leaking syringe—but, to make doubly sure, a second test, using the same dilution of Old Tuberculin, was made if the result of the first was negative If this second test was negative, a third test, using 100 T U (0 1 ml of 1/100 dilution O T) was made

The results were read at seventy-two hours If the greatest diameter of the area of induration was 6 mm or more, the test was regarded as positive

To ensure uniformity, both of us were present when the tests were made and the results read

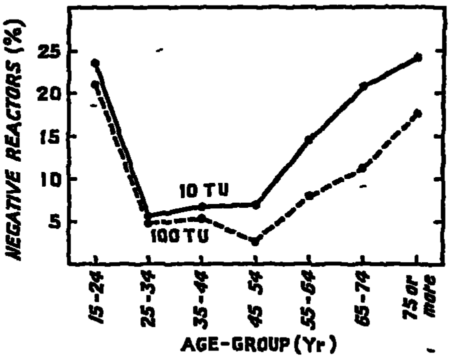

Fig 1—Negative tuberculin reactors in 1285 patients (695 male and 590 female)

Results

1285 patients (695 males and 590 females) were tested

Table I shows the distribution of negative reactors to tuberculin in successive age groups It will be seen that almost 25% were negative to 10 T U (1/1000 O T) in the age-group 15–24 In the next three age-groups the proportion of negative reactors was very much smaller, but, from the age group 55–64 onwards, the proportion increased, until in the age-group 75 or more it was similar to that in the age-group 15–24 The trend for non-reactors to 100 T U (1/100 O T) was similar Fig 1 shows this distribution graphically

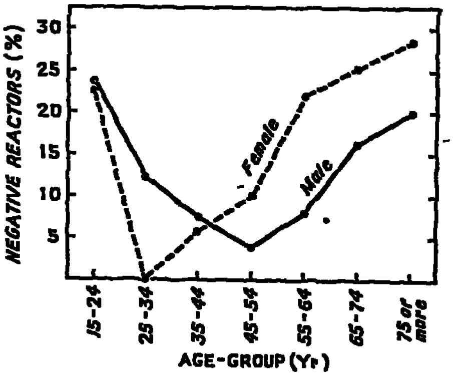

Fig 2—Negative tuberculin reactors to 10 T U according to sex in 1285 patients

Table II presents the distribution of negative reactors to tuberculin in successive age-groups for males and females separately In males there was a gradual decrease in the percentage of non reactors both to 10 T U and 100 T U from the age group 15–24 to the age group 45–54, whereas in successive age-groups over the age of 55 there was a corresponding gradual increase The proportion of female non-reactors to 10 T U decreased very

TABLE I—AGE-DISTRIBUTION OF NEGATIVE TUBERCULIN REACTORS AMONG 1285 ADULTS

Age group (yr)	15–24	25–34	35–44	45–54	55–64	65–74	75 or more
No of persons	124	105	157	228	242	230	199
Negative to 10 T U 1/1000	29 (*23 4%*)	6 (*5 7%*)	10 (*6 4%*)	15 (*6 6%*)	34 (*14 1%*)	47 (*20 4%*)	47 (*23 6%*)
Negative to 100 T U 1/100	26 (*20 9%*)	5 (*4 8%*)	8 (*5 1%*)	5 (*2 2%*)	18 (*7 4%*)	25 (*10 9%*)	34 (*17 1%*)

TABLE II—NEGATIVE TUBERCULIN REACTORS, MALE AND FEMALE, IN SUCCESSIVE AGE-GROUPS

Age group (yr)	15–24	25–34	35–44	45–54	55–64	65–74	75 or more
Males (695)							
No of persons	71	50	81	126	138	118	111
Negative to 10 T U 1/1000	17 (*23 9%*)	6 (*12%*)	6 (*7 4%*)	5 (*3 9%*)	11 (*7 9%*)	19 (*16 1%*)	22 (*19 8%*)
Negative to 100 T U 1/100	17 (*23 9%*)	5 (*10%*)	4 (*4 9%*)	1 (*0 8%*)	6 (*4 4%*)	7 (*5 9%*)	14 (*12 6%*)
Females (590)							
No of persons	53	55	76	102	104	112	88
Negative to 10 T U 1/1000	12 (*22 6%*)	0	4 (*5 3%*)	10 (*9 8%*)	23 (*22 1%*)	28 (*25%*)	25 (*28 4%*)
Negative to 100 T U 1/100	9 (*17%*)	0	4 (*5 3%*)	4 (*3 9%*)	12 (*11 5%*)	18 (*16 1%*)	20 (*22 7%*)

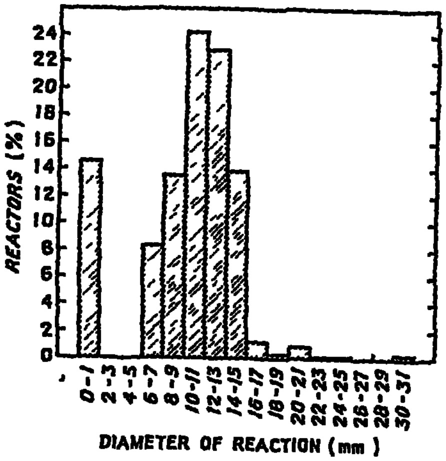

Fig 3—Reactions to 10 T U by size in 1285 patients

sharply from 22 6% in the age-group 15–24 to nil in the age-group 25–34 and increased again sharply from the age group 35–44 onwards The trend for female non-reactors to 100 T U was similar It is seen too that the proportion of non-reactors was larger among females than among males after the age of 45 Fig 2 shows graphically the distribution of non-reactors to 10 T U (1/1000 O T) in males and females

Fig 3 shows the distribution of reactions to 10 T U (1/1000 O T) by size in 1285 patients Fig 4 shows similarly the distribution of reactions to 100 T U (1/100 O T) by size in 188 patients who were negative to two 10 T U (1/1000 O T) tests Experience has shown that, in recording the size of reactions, there is a bias in favour of approximating to even numbers (Meyer 1951), in figs 3 and 4 reactions are therefore recorded as 0 and 1 mm , 2 and 3 mm , 4 and 5 mm , &c It is seen that, with both dilutions of O T , positive and negative reactions are clearly separated

Fig 5 is designed to show the influence of sex and age on the size of positive reactions For each age group the average size of reaction is shown in males and females It is seen that the average size of positive reactions in males was greatest in the age group 25–34 and progressively diminished in succeeding age groups In females the average size of reaction was greatest in the age group 15–24 and decreased progressively in succeeding age groups until it reached its lowest limit in the age group 55–64 It increased somewhat in the age group 65–74 and again in those aged 75 or more Although the average size of reaction was smaller in the older age groups than in the younger age groups, the difference was only 2 mm Histograms of the size of reactions were made for each age group of the sexes separately These displayed a well-marked mode around 9–13 mm for both sexes and for all age groups up to the age of 54 The succeeding decade showed a more even spread over 6–15 mm , and thereafter there was no constant picture

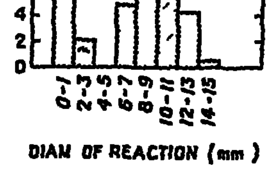

Fig 4—Reactions to 100 T U by size in 188 patients

Discussion

If the adult hospital population surveyed is representative of the population at large, it seems that, after the age of 55, the proportion of negative reactors increases with age Few published reports of tuberculin surveys include all age groups, but the results of Furcolow et al (1948) Meyer (1951), and Bellomo (1952) are similar to our own It is true that Bellomo states that the younger the individual the less likely is he to be a reactor to tuberculin, but Bellomo's figures show an increase in the proportion of negative reactors in people aged more than 60 Amazon (1943) and Coury and Marland (1948) found in old people an increase in the proportion of negative reactors in successive age groups, but that found by Coury and Marland was not striking

The comparatively high proportion of negative reactors in the older age groups in the present investigation can scarcely be explained on the basis that these people have never been infected with tuberculosis, for there is no evidence to suggest that during their earlier years they were less exposed to infection than were later generations, indeed the reverse is the case

Moreover Amazon (1943) and Groth Petersen and Wilbek (1955) found radiological evidence of previous tuberculosis in many elderly persons in whom tuberculin tests were negative Indeed Groth-Petersen and Wilbek concluded that, although a negative 10 T U test in persons aged less than 50 probably indicated absence of previous infection with tuberculosis, this interpretation could not be made in the case of persons aged more than 50 The fact that the investigations of Groth Petersen and Wilbek showed negative reactions in persons with evidence of previous tuberculosis in chest films tends to dispose of the improbable proposition that a high percentage were never infected at all

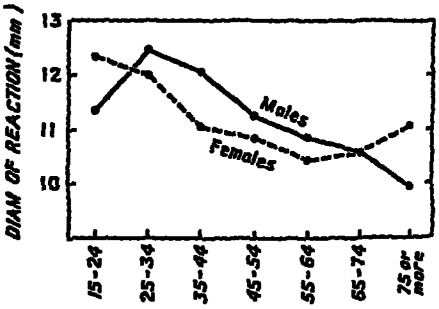

Fig 5—Average size of positive reactions to 10 T U by size and sex in 1285 patients

The increasing proportion of negative reactors in the older age groups could be explained by a waning of skin sensitivity to tuberculin with the passage of time Eventual complete loss of skin sensitivity might indicate that the tubercle bacilli in the body had died or, if still living, they had ceased to provide a sufficient stimulus On the other hand, it might simply be that, with age, the skin loses its power to react to various stimuli including tuberculin

The assumption that the reaction to the tuberculin test tails off gradually with age until it disappears is not supported by the results of this investigation It seemed that an all or none law operated In all cases in which a negative reaction was recorded to 10 T U (1/1000 O T) there was no induration at all , and in the negative reactors to 100 T U (1/100 O T) there were only four reactions with any induration, and these measured 2–3 mm , well below the 6 mm measurement required for a positive result

The significance of a positive reaction to the tuberculin test in relation to the quantity of antigen injected has been studied by Bates et al (1951) and Palmer (1953) who concluded that most reactions elicited by a small dose intradermal test (5 T U) indicated infection with tubercle bacilli, but that a positive reaction only to a large dose test, such as 100 T U or 250 T U , might be non specific They suggested that, in certain geographical areas, this large dose reaction might indicate infection by an organism antigenically related to the tubercle bacillus but non pathogenic for human beings

Palmer (1953) also found a wide scatter in the sizes of reaction to large doses of tuberculin (250 T U), making the separation of positives from negatives arbitrary In the present series there was a clear cut separation of positive and negative reactors to 100 T U (fig 4)

The morbidity and mortality from pulmonary tuberculosis in older men are comparatively large, and acute forms of tuberculosis are not uncommon in the older age-groups (Rich and McCordock 1929, Spain 1947, Ball et al. 1951, Lees and Munro 1954, Allan et al 1956) There may be some connection between loss of skin sensitivity to tuberculin and susceptibility to tuberculosis, but, as the proportion of non-reactors among elderly women is even greater than among elderly men, and the morbidity and mortality among elderly women are much less than among elderly men, it seems that other and more important factors operate

Summary

A tuberculin survey of hospital patients aged 15 or more was made, 1285 patients (695 males and 590 females) being tested

Patients with diseases or receiving treatment likely to affect tuberculin sensitivity were excluded

An initial injection of 10 T U was given followed by a further injection of 10 T U if the result of the first test was negative If this second test was negative, a third test, using 100 T U, was made

After the age of 34 in women and 54 in men the proportion of negative tuberculin reactors increased in successive age-groups

We are grateful to Dr A W Lees and Dr G W Allan for their help and encouragement, the clinicians of the Western District Hospital, Stobhill Hospital, and Ruchill Hospital for their coöperation in this investigation, and the Board of Management for Glasgow Northern Hospitals for assistance

In England Now

A Running Commentary by Peripatetic Correspondents

The view has lately been expressed that the sculpture on the proposed Government building in Marylebone should not consist entirely of mongoloid women in an advanced state of elephantiasis Why ever not? It seems a magnificent Trans-Ural gesture for reorientation of the foreign-policy facies which we present to the wider world The œdema of our dependent parts at least is realistic The fragments of our civilisation may one day be dug out of the rubble of our self-immolation to stand alongside the masterpieces of the fifth century B C in some global museum

How instructive it will be to bequeath a record of our pathology The accessory auricles and polymastia of Roman statuary will be eclipsed by the twilight genius of the Atomic Age I wonder if the new-world research-workers will divine that we carved hydrocephalic and anencephalic busts for Burlington House long before our genes mutated in the First Ionisation Period Perhaps they will feel pity for the exfoliative dermatitis of bronze portraiture, admire the acromegaly of our business tycoons, envy the androgen activity of our virile torsos Will we have time to immortalise our ladies swinging back to Titian, or shall we just scratch their vital statistics on the foundation stones of deep shelters? But some of our artistic efforts seem likely to puzzle comparative anatomists Learned arguments will flow whether our central abdominal and thoracic foramina were congenital or acquired. Our known heroic habits of pneumonectomy and splenectomy will possibly support the latter view, although experimental work will be most frustrating to reproduce our collateral circulation and famous spinal rigidity It may be left to some philosopher to guess that the vacant space is where our psyche used to perch

There is really a lot to be said for the artist capturing the impression of movement in our medical life before it gets any more fossilised of its own accord I am all for writing and carving on the walls of public buildings And if we are to combine reorientation with tradition, why not adorn the Inland Revenue with a stony statue, many-armed and palms outstretched, the spirit of our times embodied with a risus sardonicus, tongue-tied in tetanic spasm?

"Hullo," I said, "it's old Halifax! What are you doing here?"

"Just browsing"

We had been students in the same year He was a practitioner in the next town, and we met by chance from time to time—on this occasion in a second-hand bookshop We always discussed the same subject

"I heard from Herman Jones the other day," said Halifax putting down the book he had been holding "He's an orthopod now, you know"

"He would be," I remarked "I ran into Little Billie at a conference recently Do you know what he's doing? He's a general, if you please!"

'No! I see that Slinky Syme has achieved his ambition of becoming a gynæcologist in Poshmouth, of course"

"Every man to his choice Do you remember Chambers, that studious fellow? I'm surprised to see that he's a school medical officer"

"Yes I'd have thought he'd be a professor of something As for dear old Runty, who never graced any of the lectures with his attendance, he's a research wallah at some place outside London"

'Well, well! We seem either to have run absolutely true to type or to have become complete paradoxes By the way, Halifax, what about yourself? Did you not want to be a plastic surgeon, if I remember rightly?"

'Maybe I did, but it didn't work out that way What about you? You were always keen to be a doctor on one of the Hebrides, weren't you?"

"Yes, I was"

The conversation lapsed "What's your book?" I half-expected it to be *The Story of Surgery* or something like that He handed it to me without speaking *An Introduction to Economics* I read "That," said Halifax, "seems to put it in a nutshell"

* * *

Many drivers must have experienced fog vertigo while motoring Giddiness arises while the car is in motion and also on getting out of the car immediately after it has stopped In both you have an illusion of horizontal displacement in the long axis of the car While driving it leads to a false idea of speed and even of the direction of movement of the car On stepping out of the stationary car there is vertigo for a second or so in the opposite direction from the car's motion It is something like the vertical vertigo I get in a totally enclosed lift and seems to be due to the absence of adequate fixation for the eyes For instance, I find it does not occur if I can fixate on the rear lights of a car ahead or on street lights

The absence of adequate stimuli for fixation and the capacity of the brain to organise visual stimuli leads to visual illusions of almost hallucinatory quality when fog is dense but unevenly so I remember being terrified one night to see a line of tanks advancing across my path out of a dense fog on one side They disappeared as the car drew nearer and their illusory nature was confirmed No doubt fatigue also plays a part in this phenomenon, because it can occur at night without fog

It is difficult to avoid these illusions A windscreen placed far from the driver makes things worse because the eye focuses on spots and reflections of the car interior rather than the dim contours further away This can hardly be altered without rebuilding the car Simpler solutions are to keep the windscreen spotlessly clean, to shade panel lights, and even to paint the facia and controls matt black as some experienced rally-drivers do in order to prevent reflections in the screen I am told the effect is restful and has a strong functional appeal, but so far my wife has prevented me from attempting it No doubt summer will be here again before I can convince her that it is worth trying

* * *

It was the first Saturday in March, the day that summer came to London just nine months late At 5 P M I was about three-quarters through a long clinic which had already lasted three hours A patient came in, "Lovely weather you are having," he said "And so are you," I replied, making what I thought was an apt rejoinder 'But I have had to work in it," he retorted

* * *

Our sanatorium is on the moors, a couple of miles from the nearest little town, and we have a bus to transport the staff There is a proper bus-stop in the main street where the passengers get on and off The bus is irreverently known to the townsfolk as the Tubercular Circular

* * *

St Cynthia's Hospital, Delphi —Applications are invited for the post of SENIOR REGISTRAR for general medical duties, *including the care of patients The appointment will be made* for a probationary period of 1 year, after which the successful candidate will have charge of beds and consultant status will follow on the retirement of the present senior physician in 3 years There will be no opportunities for teaching or unoriginal research

Applicants should have engaged in active medical practice for more than 8 years, of which at least 6 years should have been spent outside a teaching hospital The post demands sound clinical judgment, high competence, wide experience, and familiarity *with modern medical thought, and possession* of the M R C P is a disadvantage Canvassing and the submission of references and testimonials will disqualify, and applicants are expected to furnish proof of their abilities There will be no formal interview but it is incumbent on candidates to call upon each member of the selection committee composed entirely of the senior medical staff of the hospital Arrangements may be made through the hospital secretary to ensure that the interviews are completed in the same day Where it is intended that published work should be taken into consideration, one reprint of each article should be submitted in advance, and such work will be judged on its merit

Applications (one copy) should reach the Medical Director by 17th March, 1997

Letters to the Editor

X RAYS AND LEUKÆMIA

SIR,—In our preliminary communication [1] we reported the existence of an association between diagnostic irradiation during pregnancy and later development of leukæmia or cancer in the child Dr Reid (Feb 23) has revived the suggestion that this association might depend simply on a coincidence between two otherwise unrelated facts (*a*) that primiparæ are more likely than multiparæ to be referred for radiography, and (*b*) that first-born infants may be more liable than others to develop malignant disease during childhood Our records confirm the truth of both (*a*) and (*b*), hence Dr Reid's explanation has a certain prima facie plausibility However, as previously reported,[2] a higher incidence of antenatal irradiation is still found among our cases when comparison is restricted to controls of corresponding parity The case/control contrast is in fact just as great after standardisation for parity (and for the proportion of twin births) as when this factor is ignored The risk associated with primogeniture and the risk associated with antenatal irradiation are therefore two quite distinct entities

Dr Reid is justified in stressing that, on the evidence of our figures, over 90% of the cases of malignant disease in children under 10 years of age (which are in any case rare) must be due to causes other than diagnostic irradiation It follows that the risk *to* life associated with irradiation in utero must be *small*, nevertheless our report has a practical implication if the risk of *not* performing an antenatal X-ray examination is also small

Two other reasons for exercising greater caution in this matter than Dr Reid yet feels to be necessary should also be mentioned In the first place there is the small but inescapable genetic damage to be considered According to Osborn's estimate [3] just over a quarter of the genetically significant radiation resulting from diagnostic radiology is received by children before they are born Secondly, *it is not safe to assume that* the cases of leukæmia and cancer which occur within the first decade of life represent the whole "first generation" cost of exposing fœtuses to X rays The data on leukæmia following the atomic explosions in Japan do not give "any clear indication that the incidence has yet begun to diminish by the end of the ninth year" [4] In seventeen confirmed cases of malignant disease following irradiation for thymic enlargement the *average* interval between treatment and onset was nine years [5] Our own data also suggests that the *relative* risk of death from malignant disease for children who are irradiated in utero is as high as ever after eight or nine years even *though the absolute* risk has diminished by these ages

COST OF HOME CARE FOR THE ELDERLY

SIR,—I read with interest your note on this subject (Feb 23, p 435) Nearly two years ago the borough treasurer of Reading and I compared the cost to both national and local public funds of maintaining an elderly person in a new bungalow with that of maintaining him in purpose built part III accommodation We postulated two visits per week from a district nurse and a varying number of hours per week from a home help *It became* apparent that in such a situation it was cheaper to main tain an elderly person in the part-III accommodation once he required more than fourteen hours' domestic help per week.

---

[2] *Ibid* p 573
[3] Osborn S B *In Hazards to Man of Nuclear and Allied Radiation* H M Stationery Office 1956, p 117
[4] *Ibid* p 86
[5] Simpson C L et al *Radiology* 1955 64 840

I endorse the hope of the governors of the National Corporation for Old People that further attempts will be made to compare the cost of institutional and domiciliary care of the elderly This subject grows in importance as more and more old people require help from central or local public funds. There are cogent reasons why the elderly should not be admitted into institutional accommodation, whether hospital or part III, but I wonder whether some people are not assuming too readily that it is cheaper to maintain them outside such accommodation Unfortunately the issue is often clouded by the distinction between local and central government services.

BRONCHIAL CARCINOMA

SIR,—It was with interest that we read Mr Vernon Thompson's letter (Feb 23) giving figures to show the time taken to refer cases of bronchial carcinoma to a thoracic surgical unit As physicians who specialise in diseases of the chest we were surprised at the delay which arose at the chest clinic This has, therefore, led us to analyse our cases seen at the chest clinic at this hospital during the past three years They total 75 and can be divided into three groups

The first is made up of 38 cases where at the first clinical examination bronchial carcinoma was diagnosed but which were judged to be inoperable because of metastases outside the chest or because of poor general condition with, for example, chronic bronchitis and emphysema. Most of these cases were discussed with, and many investigated by, our thoracic surgical colleague The diagnosis was confirmed in as many cases as possible by bronchoscopy, or gland biopsy, or sputum examination, so that we could speak with certainty to the relatives and plan appropriate treatment with the family doctor

The second group is made up of 28 cases in which when they were first seen, or shortly afterwards, "probable carcinoma which might be operable" was diagnosed clinically and the patients were immediately referred to a thoracic surgical unit for further investigation and treatment In this group the surgeon found 15 to be inoperable at bronchoscopy or thoracotomy, resection was possible in the remaining 13

There is a third group of 9 cases in which the diagnosis was delayed because the development of the carcinoma was masked by various other conditions

It can be seen from the accompanying table that of 75 cases 59 were diagnosed immediately and a further 7 within six weeks. In 9 cases the diagnosis was delayed The average time taken for the 28 cases in which the patients were admitted for operative assessment was three weeks, of which investigation at the chest clinic accounted for three days

ANALYSIS OF CASES OF BRONCHIAL CARCINOMA AT A CHEST CLINIC

—	Delay in diagnosis (weeks)								
	0	1	2	3	4	5	6	>6	Totals
Inoperable on clinical examination	35			1	1	1			38
Inoperable on bronchoscopy or thoracotomy	14						1		15
Resections	10	1	2						13
Delayed diagnosis								9	9
Totals	59	1	2	1	1	1	1	9	75

The third or late-diagnosis group included 3 patients with known tuberculosis in which the average time for diagnosis was three months A further man was under observation for eleven months on account of a small lesion considered to be tuberculous This cavitated and tubercle bacilli were reported in his sputum Since the cavity became appreciably larger despite three months chemotherapy lobectomy was done and a cavitating carcinoma found. A case with bronchitis was observed with a slowly increasing area of infiltration This was thought to be tuberculous, but after seven months a bronchoscopy showed a squamous-cell carcinoma Operative treatment was precluded because of bronchitis, but the patient responded well to radiotherapy It took us nine months to diagnose carcinoma which occurred in a woman who was under treatment by us for acute systemic lupus erythematosus, with pulmonary manifestations (in the press) One case presented as an empyema at the site of a known bronchiectatic lobe, and an underlying carcinoma was not recognised for nine weeks In an elderly bronchitic man collapse of a lobe developed after he had been under observation for five months, carcinoma was diagnosed clinically, but his general condition did not allow further investigation In a further, uncomplicated, case diagnosis was delayed for six months, during which time he was seen by locums

Mr Thompson, in order to avoid delay, advocates an X-ray service so that general practitioners can refer cases directly to a thoracic surgical unit In the majority of our last group it is unlikely that this would have happened on the appearances of the initial radiograph

The adequate recognition of carcinoma of the lung is only a part of the adequate management of chest diseases in general This can be carried out at chest clinics only if they are staffed by well-trained people and have efficient radiological and laboratory facilities

There was little or no delay in the diagnosis of most of our cases, yet the number helped by surgery was small This is because the disease has an insidious onset, tends to occur in elderly patients who are commonly disabled by chronic bronchitis, and is often well advanced by the time the patient attends the chest clinic

The success of surgery depends mostly on the histological character of the tumour Many patients with slowly growing tumours, such as squamous-cell carcinoma, do well with surgery despite long histories

Ashford Hospital
Ashford Middlesex.
P E BALDRY
B GOLBERG

SIR,—Mr Thompson analysed 135 cases of lung cancer operated on at the London Hospital in 1954 and found an average delay of 6 4 months between first symptom and attendance at the department of thoracic surgery He blames chest physicians for much of the delay in diagnosis Apparently all cases came to him through a chest clinic and not one direct from a general practitioner or general physician This is unusual and does not obtain in our area In previously published larger series, a similar delay before operation has been reported. Most of these reports relate to the days before the development of the modern chest clinic, and thus the delay referred to by Mr Thompson is shared with other physicians radiologists, and general practitioners

The prognosis of cancer of the lung paradoxically appears to improve with the delay before operation, and thus careful assessment before surgery and exclusion of other disease is reasonable In the Midlands, the commonest cause of hæmoptysis is chronic bronchitis It would be impracticable for a thoracic surgeon to see all cases with this or other symptoms of chest disease which so frequently occur in middle aged or elderly men

With the concurrence of thoracic surgeons in this area, some chest physicians bronchoscope possible cases of cancer of the lung within ten days of first consultation Before this cytological examination of the sputum will have been made Consultative sessions between thoracic surgeon and chest physician are regularly held in a chest clinic or thoracic surgical unit, and the patients are operated upon as soon as there is a vacant surgical bed—the total delay is usually rather less than two months

We suggest that facilities for expert cytological examination of the sputum should be extended Bronchoscopic examination by either physician or surgeon should be commonplace and widely available Radiography of the chest is more important than auditory examination, and we entirely agree that radiographic facilities for general practitioners should be provided At that stage, it should not be necessary for cases to be filtered through either a physician or a surgeon

Worcester E N MOYES
Warwick P G ARBLASTER

SIR,—Mr Thompson has rightly castigated the chest physicians for delay in sending patients with bronchial carcinoma to the thoracic surgeon This indictment must apply not only to the chest physician but also to the bulk of the medical profession

A normal chest X-ray by no means excludes the presence of bronchial carcinoma, but it is perhaps asking too much either of the radiologist or the general practitioner to discriminate between those patients who should be referred to the thoracic surgeon and those who may safely be discharged from surveillance

At this clinic it is our normal practice, whether or not the chest X-ray is normal, to investigate in the following manner all patients with hæmoptysis of unknown cause and all patients aged 30 or more who have recently had a localised pulmonary lesion noted on clinical or radiological examination (1) immediate bronchoscopy and if necessary bronchography, (2) for six months, monthly clinical and radiological review, (3) for three years, clinical and radiological review at three-monthly intervals We would stress that these investigations are essential even in the presence of a normal chest X-ray Only if patients are investigated in this way can we hope to diagnose the early bronchial carcinoma

Baguley Hospital, Manchester P F JONES
T M WILSON

SIR,—Attacks on colleagues such as that made by Mr Thompson are fortunately rare However, it is pleasing to find that some thoracic surgeons realise that an operable case of bronchial carcinoma is urgently in need of treatment Delays in admission to a thoracic surgical unit of upwards of four weeks are common, and we wonder what would happen to the waiting list if only cases with a doubtful chest radiograph were admitted direct to such units The main factor in the early diagnosis of bronchial carcinoma is always to keep such a diagnosis in mind Symptoms commonly precede radiological changes, and the institution of further investigations should not be delayed because radiological examination is negative

Edgware General Hospital Middlesex R GRENVILLE-MATHERS
H J TRENCHARD

SIR,—Mr Thompson seems to take an unduly pessimistic view of the work done in the chest clinics in this country

There must be many chest physicians who, like myself, were trained by him and who are capable not only of diagnosing bronchial carcinoma on clinical and radiological findings, but of proving the diagnosis by bronchoscopy should it be necessary to do so In spite of this the sad fact remains that of 16 cases of proved bronchial carcinoma picked up during the first few months of our general practitioner referral miniature radiograph service, none has proved operable The average delay between miniature radiograph and bronchoscopy has been about three weeks Is it possible that the publicity campaign in the press is having the opposite of the desired effect ?

I have gained the impression that patients who really fear that they have a carcinoma of bronchus are afraid to go to their doctors to have the diagnosis proved and that in many cases the delay is in the period before reaching the general practitioner

Croydon Chest Clinic D PARADISI

THE DISINTEGRATIVE ACTION OF THE NERVOUS SYSTEM

SIR,—It has long astonished me to hear it repeatedly stated that modern medicine is "integrative" and "holistic" and that the tendency is for it to become more so, when in fact, exactly the opposite is the case Medical science in the twentieth century is essentially analytical and disintegrative as progressive specialisation clearly indicates, nor is this to be deprecated, for it is in this very power to isolate and deal with the multiplicity of factors affecting a person's well being that the power of medicine lies

The emergence of psychological medicine as an effective force, whatever its philosophical implication is just another specialty, in practice, another "system" the disorders of which have to be correlated with the rest

This extraordinary confounding of opposites is, surely, an expression of our revulsion against 19th century materialism and its consequent tendency to degrade human values Holistic and similar integrative philosophical systems serve to reassert in our minds the unique intrinsic value of each individual, and hence determine our attitude towards our patients, and our profession But this, Sir, is Faith Science is a different matter

London, S W 11 J F ROBINSON

UNMARRIED PARENTHOOD

SIR,—It is hardly proper for someone from "a moral agency dabbling with sex" to intervene when one doctor accuses another of unphysiological thinking every profession has its courtesies I may, however, perhaps ask Dr Tuthill (Feb 23) what he means by morality, Does he assume that "what is moral" means simply "what most people do" ? If there were a tendency for more and more swindlers to come before the courts would that fact make swindling more "moral" than before ? If more and more patients die of cancer of the lung, are we to revise our standards of health, and regard that cancer as a normal condition of civilised man ?

This pathetic appeal to "changing circumstances and increasing knowledge" as a means of slipping off our obligations is surely discredited by now This Council is so concerned with accurate knowledge that our workers were able to supply some of the statistics from which this discussion arose but the statistical method is not the whole of philosophy There has to be a dogma at the heart of morality—a belief by which peoples or nations determine to live, first because they believe it to be true, secondly because they see that it makes sense of the knowledge they have The dogma at the heart of Christian sex morality is that coitus is a sacramental act for the expression and enrichment of a partnership to which a man and a woman have committed themselves irrevocably in love, and for the procreation of children within that partnership, and there alone

This dogma does justice to the wholeness of human nature we do not regard our bodies as cleverly contrived toys, to be played about with for the sake of thrills, we do not limit our concept of sex to genital activity, nor have we only negative counsel for lovers who have to wait for their marriage Our dogma, which carries of course, its own discipline within it, meets the facts of human nature and of human and social need, and its confirmation is amply demonstrated in the history of civilisations as well as in the consulting rooms of responsible psychiatrists The facts which appear to have alarmed your correspondents so immoderately are because our dogma is ignored they afford no ground for argument that it should be revised

Without this dogma, in fact, sex becomes like an organ enlarged, a faculty uncoordinated with the rest of personality; men and women are tantalised, then cheated of that which they most hope for, children suffer the injustice of being born unwanted or without a natural home, women are exploited—in the long run, the woman pays most in societies which loosen sexual morality, and society itself drifts into those very barbaric and subhuman notions which seem to underlie Dr Tuthill's letter—that sex is but an appetite analogous to that behind eating and drinking, that the "tragedy" of the unmarried mother is not "very serious" while the adoption societies cannot meet the demand for all the babies which she can produce (an interesting variant, by the way from the attitude of your other correspondents for whom the illegitimate child appeared to be the *only* tragedy in premarital intercourse)!

A healthy society is not ashamed to affirm the basic principles by which it lives. What we want, do, and are depends on what we believe

PEDICULOSIS CAPITIS

SIR,—As one who looked after the fate of a large part of Dublin's louse population in dermatological practice during six years, I was interested in the findings of Dr Nelson and Mr Cromie (Feb 23) in regard to the superiority of 'Esoderm' over other remedies for pediculosis capitis As they note, by far the most important aspect of this condition is the frequency of reinfestation Of my last 500 hospital cases, 20% suffered from pediculosis capitis (apart from any other skin disease) and of these about a third (7%) had become reinfested

The head louse is common among poor families in Dublin and, as a great many of them cannot afford shampoos, a cleansing agent such as esoderm would be extremely useful But the problem is obviously one to be dealt with principally by improving living conditions, and by education in hygiene, and will not be solved by insecticides The idea, therefore, that the nursing staff of the school and public-health services should be one is excellent

I may add that it is well recognised that, in young patients from the poor areas of Dublin, dandruff is nearly always mechanised.

London W 1   **BETHEL SOLOMONS**

TOWARDS PREVENTING SUICIDE

SIR,—I was most interested in the letters published in your columns relating to the detection and prevention of would-be suicides

It has long been a theory of mine that many suicides could be prevented by the creation of a society on similar lines to Alcoholics Anonymous

That is to say, a permanent service would have to be established which would be prepared to accept calls from any person who was desperate and seeking help In many cases suicide would be prevented if the would-be suicide could find a sympathetic listener and counsellor who would listen to all his troubles and give him assistance and encouragement Once it became generally known that such advice and help were forthcoming and would be suicides were urged to get in touch with the society and to suspend any drastic action at least until a member of the society should have time to call on them within the next 24 hours I believe the psychological effect—even if only a natural curiosity to know how the counsellor would react to the problem—would cause them to hesitate Of course it would be essential that such a service should be a night and day service with an easy telephone number to memorise and voluntary helpers in all the larger towns Such helpers should not belong to medical or religious bodies, nor should they be trained social workers or psychiatrists but simply men and women who have themselves known troubles and overcome them and who have both experience and understanding Preferably, of course, the root cause of the trouble should be ascertained before sending the counsellor (in such general terms as ill health, money matters, business, love affair) so that a person could be chosen to help who had overcome a similar problem in the past

Could not such a scheme be started under the auspices of some interested organisation?

Paris.   **A WATNEY**

OLD PEOPLE IN HOSPITAL

SIR,—I am sure everyone will agree with Dr Trevor Howell's remark last week that there is frequently a social problem behind the admission of elderly patients to hospital Solving this problem is usually difficult, but not impossible a proportion, however, remain insoluble, at least to me It is these patients, or rather ex-patients, who constitute the more or less permanent residents to whom Dr Rang refers (Feb 23)

Of the 32 beds available (only 26 were filled at the time of Dr Rang's experiment) over 20 are filled with elderly persons suffering from a profound disability which does not, however, require skilled nursing care They have no relatives, or none willing or able to take care of them, while the local authority either considers their disability too severe for admission to a welfare home or pleads lack of accommodation Failing a more generous interpretation of the meaning of Section 21 of the National Assistance Act that "it shall be the duty of every local authority . to provide accommodation for persons who by reason of age, infirmity or any other circumstances are in need of care and attention which is not otherwise available to them" or the provision of more such accommodation by the local authority, it is difficult to see how this anomaly can ever be remedied

London, S W 1   **AMULREE**

POLYNEURITIS AS A CAUSE OF "AMYOTONIA CONGENITA"

SIR,—Dr Chambers and Dr MacDermot have rendered a signal service in delineating (Feb 23) the diagnostic features of infantile polyneuritis Less praiseworthy, in my opinion, is their choice of heading They clearly regard amyotonia congenita as a miscellaneous group of conditions, having in common only their occurrence in infancy or early childhood and the generalised hypotonia exhibited by those affected This is a distortion of Oppenheim's original concept and obscures the very real advance which his contribution provided

This consisted in drawing attention to a condition of generalised muscular hypotonia in infants, dating from birth and showing a tendency to gradual improvement Oppenheim believed it was a disease-entity and due to delayed development of the muscles including their innervation. He anticipated therefore, that the muscles would appear normal on orthodox histological examination. Much of the confusion over the nature of this condition is the result of other conditions, now better defined and more easily recognised, having been incorrectly diagnosed as amyotonia congenita I am particularly referring to cases of Werdnig-Hoffmann disease, of congenital or intra uterine onset being mistakenly diagnosed as amyotonia congenita If there do, in fact, exist *formes frustes* of Werdnig-Hoffmann disease, as suggested by Arthuis,[1] muscle biopsy may be required to make the correct diagnosis In infantile polyneuritis, as Chambers and MacDermot so usefully point out, an elevated protein content in the cerebrospinal fluid may be sufficient to make the diagnosis clear

It is quite possible that Oppenheim himself wrongly diagnosed as amyotonia congenita infants with one of these other conditions. No one is infallible Nevertheless, the fact remains that there is a small group of infants who show all the clinical features of amyotonia congenita, as described by Oppenheim,[2] including congenital onset and tendency to improvement, and also yield muscle biopsies entirely free from abnormality of the muscle fibres (6 cases recently reported by Walton[3] under the heading of benign congenital hypotonia) and with completely normal intramuscular nerve endings[4] or at the most an appearance of immaturity[5]

---

[1] Arthuis M L'amyotrophie spinale *infantile* de Werdnig Hoffmann, Paris 1954

[2] Oppenheim H *Mschr Psychiat Neurol* 1900, 8, 232

These cases may in time be shown to have more than one ætiology, but as long as there remain obscure cases of congenital hypotonia with normal muscle histology and favourable outcome, the application of the term *amyotonia congenita* is still appropriate To give new names to these cases (e g, essential and primary hypotonia of young infants,[6] delays in the appearance of tone,[4] benign congenital hypotonia[3]) is not to throw new light on their essential nature, but merely gives the uninitiated reader the impression that new diseases have been described

I would therefore submit that a more suitable title for this otherwise excellent paper would have been "infantile polyneuritis simulating amyotonia congenita"

PROTECTION OF TESTES IN DIAGNOSTIC RADIOLOGY

SIR,—In an annotation last week you refer to the need to reduce the radiation dose administered by diagnostic methods without diminishing their efficiency

Most diagnostic X-ray departments do not seem to take any special precautions to protect the testes from irradiation when films are taken of the pelvis or neighbouring organs Though the genetic risk from such exposure is small,[7] it could be diminished greatly by shielding the testes as a routine This should not present undue technical difficulty, it seems unreasonable to wait for evidence to show just how much genetic damage can be done by low-dose irradiation of human testes

ANDREW HERXHEIMER

RHEUMATOID ARTHRITIS WITH CHRONIC LEG ULCERATION

SIR,—I fear that Dr Allison and Dr Ray Bottley (Feb 9) have drawn quite unjustifiable conclusions from their failure to heal chronic leg ulcers in rheumatoid patients In the past three years I have seen four cases similar to those cited by them The record of the fourth patient, at present under treatment is as follows

A housewife, then aged 30, began to have rheumatoid arthritis in 1920 After seven years' anti-rheumatoid treatment an ulcer appeared on her right leg This did not heal until fifteen years later—and then only when she had been in bed after the removal of a stone from her right kidney Her rheumatoid arthritis steadily increased in severity, and in 1948 she was further crippled by an ulcer on the left leg (the right meanwhile remaining completely healed) In the past eight years she has had no less than four unsuccessful skin grafts, interspersed with numerous long periods of bed rest in hospital Eventually the ulcer encroached on two-thirds of the circumference of the leg above the ankle, at this stage amputation was advised—and refused

When she came under my care, twenty weeks ago, her ulcer measured 270 sq cm in area (18 × 15 cm) She was (and still is) very severely deformed by rheumatoid arthritis, with virtually no free ankle movement She had reached the stage of walking almost on hands and feet, using the backs of her proximal phalanges as forepaws This was so obviously a chronic ulcer resulting from venous stasis consequent on loss of lower-limb muscular activity, that a confident prognosis could be given immediately and she was ordered to bed—despite her protests that this had been tried many times before (as with the Middlesex cases) After two weeks of this regime the ulcer measured 180 sq cm, after six weeks 100 sq cm, after twelve weeks 21 sq cm, after sixteen weeks 10 sq cm At present it is 4 sq cm in area and I expect it to be soundly healed in six weeks

Why should this be so when previous bed rest had proved so unsuccessful? The answer is quite simple—it was not bed rest in the hospital sense of the term

When a patient is put to bed, as treatment for an ulcerated leg, everyone imagines that the aim is to rest the leg—hence the term "bed rest" This is a complete misconception, for this mode of therapy should involve an *active* process—namely, promoting venous return and thus abolishing the interstitial tissue œdema which is preventing healing A patient who is allowed to wander in and out of bed from time to time is not doing this A patient sitting up in bed, even if she never gets out of it, is doing her ulcer about as much good as by standing in a queue The only way to promote venous return in bed is to have the patient lying flat (one pillow for the head) and the foot of the bed raised at least 9 inches, for it is only then that the heart level is below that of the leg, the peripheral veins cease to be distended, and the venous pressure becomes consistently negative

I suggest that the diagnosis of lupus erythematosus cannot yet be sustained in the cases described by Dr Allison and Dr Bottley

ANTI-HISTAMINE DRUGS IN CHOLERA

SIR,—In 1952 I described the prevention and cure of uræmia in cholera, by means of intravenous administration of vitamin C and intramuscular injection of an anti-histamine drug in the kidney region.[1]

In the epidemic of 1954 three anti-histamine drugs were administered separately without vitamin C (Previously vitamin C alone had failed to start urination in 30% of uræmic cases[1])

The anti-histamine drugs tested were (1) mepyramine maleate ('Anthisan'), 2 ml of 2·5% solution, (2) chlorpromazine hydrochloride ('Largactil'), 12·5 mg in 6 cases and 6 mg in 5 cases, and (3) promethazine hydrochloride ('Phenergan'), 2 ml of 2·5% solution 55 culture-positive cases of cholera with established uræmia were studied

Mepyramine failed to start urination in 3 of 11 cases (27%), chlorpromazine failed in 2 of 11 cases (18%), promethazine failed in 1 of 17 cases (6%) In 16 control group cases there was no urination in 4 (25%)

Thus the group treated with mepyramine (given alone) fared no better than the controls Chlorpromazine possibly gave slightly better results, but it was found to have a special drawback in cholera, causing a dangerous depression of blood-pressure By contrast promethazine seemed to be of definite help, and its administration led to no untoward reactions

We made extensive trials of combined treatment with vitamin C and promethazine in the severe cholera epidemics of 1955 and 1956

In all cases where urination did not occur within two hours after infusion of saline solution, promethazine was given intramuscularly in the kidney region Patients who did not urinate within the following eight hours were given vitamin C 500 mg intravenously In a few cases administration of both the anti-histamine drug and the vitamin C had to be repeated every twelve hours

Since 1954, as was then anticipated, there has not been a single uræmic death in my ward In 1955 and 1956 cases of cholera treated here numbered 1610 and 1175, and the corresponding mortality rates were 7% and 4·7% This is in sharp contrast to the figures for Calcutta as a whole (elsewhere in the city treatment is by saline infusions only), the figures for 1955 and 1956 being 32% and 36·5%[2]

DISCREPANCIES IN THE ERYTHROCYTE-SEDIMENTATION TEST

SIR,—The explanation quoted by Dr Groen (Feb 23) is not applicable to the discrepancies in the E S R test we described (Feb 2) This is made clear in the last two paragraphs under the subheading " Results " We have now seen discrepancies (arithmetical difference between duplicates) in citrated blood of 40 mm, 26 mm, and 18 mm, in addition to less serious ones

We regret that we did not refer to the valuable paper by Strom[4] Our article, however, was primarily concerned with the frequency and possible clinical significance of the discrepancies in rheumatic fever

EFFECT OF UNABSORBED RADIOGRAPHIC CONTRAST MEDIA ON THE CENTRAL NERVOUS SYSTEM

SIR,—Mr F L Davies[5] has detailed the adverse effects of unabsorbed contrast media in the subarachnoid space He emphasises the desirability of removing as much of the oil as possible after myelography or during operation

He is particularly concerned with " diminishing the chances of the substance entering the cranial cavity " Since this is most likely to occur after cervical myelography, I wish to draw attention to the technique of this examination I have described,[6] which prevents the flow of oil through the foramen magnum, no matter how extreme the degree of Trendelenburg position employed The principle consists in the maintenance of hyperextension at the atlanto occipital joint throughout the examination

MUNCHAUSEN'S SYNDROME

SIR,—The following case of this condition may be recognised by some of your readers

A red haired cook or post office worker, aged 44, appears in the casualty department with a history of increasing headaches, vomiting, drowsiness, and rapidly deteriorating vision The optic discs show changes that, to the uninitiated, appear sometimes to be those of optic atrophy, and at others those of bilateral papillœdema, the visual fields are grossly constricted She is very obese and states that she has been gaining weight rapidly, and she is usually somewhat reluctant to come into hospital

X rays of the skull show two round burr holes in the anterior frontal region the history she gives to account for these is that she had an accident some years ago and " a clot of blood " was removed from the brain She also has a much-scarred abdomen with a discharging sinus, alleged to be due to an old tuberculous peritonitis

When surgical measures to relieve the increased intracranial pressure are suggested, she discharges herself from hospital, but discharge can be achieved more rapidly by confronting her with her previous admissions to hospital I have seen her twice at this hospital, and also twice at Mile End Hospital, and a casualty officer there recognised her as having attended his old hospital, Charing Cross She has also been in Hillingdon Hospital The frontal burr holes for prefrontal leucotomy were I believe made at a hospital near London Obesity is an occasional complication of this operation, as well as an occupational hazard of cooks The fundal changes are those of opaque nerve fibres which almost surround the disc on both sides and make the patient instantly recognisable

DRINKING SEA-WATER

SIR,—Three men were rescued a short time ago after drifting for six days on a raft in the Mediterranean They are reported to have followed the " Bombard system " and drunk measured amounts of sea-water, as they had no fresh water[1] Their story has naturally received considerable publicity, and the inference is usually drawn that they survived because they drank sea-water I believe they were lucky to survive in spite of it, and, in view of the importance of this question to future castaways, I should like to present the results of some calculations I have made

From the point of view of a castaway the important question is whether drinking sea water increases or decreases the time he can survive without fresh water A direct experimental answer to this obviously cannot be obtained for man, all one can do is to attempt to calculate from experimental data how nearly a lethal point has been approached (A study of mortality in lifeboats after sinkings during the late war[2,3] does, however, provide a very convincing "natural experiment ")

Suppose first that the men had not drunk sea water In a climate such as that over the Mediterranean, which is a favourable one for survival as it is neither cold enough to cause death from cold nor hot enough to cause sweating, an inactive man without food or water loses about 1 3 litres of body water a day[4] This comes to 7 8 litres in six days, or 11% of an average body-weight This loss might incapacitate a man, but it is well inside lethal limits Adolph and his associates[5] considered a loss equal to 20% of the body's weight, incurred rapidly in the desert, likely to cause death, more severe dehydration can probably be tolerated if the loss takes place slowly So far as death from dehydration is concerned, it appears that if the men had not drunk sea water they should have been able to survive for about twice the time they actually were adrift Further calculation based on the excretion of electrolytes by fasting and dehydrated men[6] shows that in six days the osmolar concentration of their body fluids would have risen by 10%

The castaways are stated to have drunk 3 tablespoonfuls of sea water every two hours from 6 A M till 8 P M, which amounts to 12 fluid ounces a day The salinity of the Mediterranean is 3 7–3 8%,[7] and so in six days they would have taken in 2 litres of water and 2600 milliosmols of electrolytes, predominantly sodium chloride If this had been retained in the body, the overall water balance would have been improved by 2 litres but the osmolar concentration of the fluids of the body would have risen to 28% above normal. Furthermore, sodium is largely confined to the extracellular space, and this would be expanded, at the expense of cell-water, which would be depleted by a third of its volume The available experimental data[6,8,9] suggest that, after the first day of drinking sea-water, increasing amounts of the ingested salt are excreted, at the cost of body water Calculation based on the salt excretion and urine volumes found experimentally suggests that at the end of six days the concentration of the men's body fluids would have been 24% above normal Their overall water balance would be about the same as if they had not drunk sea water, but their cells would have lost proportionately twice as much water as their extracellular fluids Death can probably be caused by severe hypertonicity alone, or by severe loss of cell water, or by a combination of lesser degrees of both changes[10–12] The *combination calculated is probably not far short of a lethal level*, and it is certainly worse than if the sea water had not been drunk Furthermore, the rate at which water was being lost in the urine would be increasing, and at any later time even the overall balance of water would be worse than if sea water had not been drunk

Theory thus suggests that, although survival for six days is not incompatible with the amount of sea water these men drank, it is unlikely that they could have survived for much more than a day or so longer, as compared with the several days possible if they had not drunk sea water Even if drinking sea-water does lead to increased well being in the early stages, all the evidence is that its late effects are disastrous Castaways *cannot know the duration of the "experiment"* in advance, and they should on no account drink sea water

PAUL E POLANI

GOVERNMENT AND PROFESSION

SIR,—Your excellent editorial last week suffers from two main defects One is a defect of memory on previous occasions the threat of mass withdrawal has been effective and has not harmed the profession, so the argument that it is an alien procedure falls to the ground The other is that the idea you put forward in its place—of individual resignation—is perfect, except for the fact that terms of service and remuneration are negotiated centrally, and not individually, and that individual resignations are therefore of no value

What is more serious is the way in which you attempt to rally the "fainthearts" and give them justification *for not following their colleagues*

I know *The Lancet* tries to be objective and fair Unfortunately the profession faces a situation where "reason" is not likely to be triumphant It is the most serious situation the profession has ever had to face Literally it is that we must stand absolutely united and meet force with force or perish It grieves me that the editor of a responsible medical journal should not realise what the issues are

Two (or is it three ?) wars ago I sat in the fastness of G H Q in an administrative post I set myself two maxims *(a)* my colleague—who is also a doctor—at the scene of operations knows the right answer and it is my duty to help him to get what he needs, *(b)* the Government is always wrong Those same maxims hold true today

London W C 1

J L McCALLUM

SIR,—Your leading article last week suggests that, rather than a complete withdrawal from the National Health Service, only those general practitioners who are dissatisfied with their lot should resign

From the press and other reports, it would seem that the majority of doctors are dissatisfied with the present scale of remuneration, but, come what may, they have guaranteed that their patients will not suffer as a result of whatever action they may take

The public has now become used to a service from which it can obtain free medical attention and advice and drugs at a nominal cost A return to private practice on the part of their doctor would merely send them along to a neighbouring practitioner remaining in the service

This is especially true in the poorer urban areas—in which many dissatisfied doctors practise—where the patients might find it difficult to find the money for consultations and visits and impossible to pay for the new and expensive drugs which have been produced since July 5, 1948

The matter is an economic one, it is political only in that our pay comes from Treasury sources Should present conditions continue, the standard of medical practice can only deteriorate

Liverpool

MERVYN GOODWIN

"DOCTOR"

SIR,—There are good reasons for patients using the title of doctor when describing physicians and surgeons who may not hold a university doctorate degree, and at the present time it is well to remember them Past generations of general practitioners, as well as our surviving elders, have been the only freely accessible men with a higher education and integrity Because of this, patients brought problems, *demanding time* sometimes expense, and always wisdom, that were far removed from medicine or surgery They were, and sometimes are still, too uncomfortable in the company of the priest, too frightened of the police, and too timid to consult their headmasters Politicians might be hard to trust, the lawyers they could not afford Their doctors were on their side, and patients found that doctors would care for them and their problems without thought for themselves

I believe this to be true especially in this country, and perhaps it is a pity that in this country the qualifying degree is not a doctorate in medicine It might remind us of our heritage and assure patients who might be disturbed in changing times

We need to be reminded that our profession is concerned with an ideal rather than materialistic way of life It is a service However excellent our auxiliary help, we must preserve our right to attend confinements of our patients, to vaccinate and inoculate those whose parents wish us to do it, and to attend old people and report our own cases to geriatric centres So to those who say that family doctors will not provide for geriatric clinics, clinics for school children, and infant and maternity patients unless they are paid extra for doing so, we must reply that all these are being done now without this extra payment

Does the public connect with the title of doctor a code of ethics and a sense of service beyond which might be considered reasonable by a physician and surgeon ? This is important, because to disillusion the public in this would bring discredit, It behoves the public and each of us to have the faith that doctors have the highest standard of service and code of behaviour To lose this and receive badly needed financial assistance will be no victory Doctors do not strike

Parliament

Royal Commission on Remuneration

On Feb 28 the Prime Minister announced that this commission would have the following terms of reference

To consider (*a*) How the levels of professional remuneration from all sources now received by doctors and dentists taking any part in the National Health Service compare with the remuneration received by members of other professions, by other members of the medical and dental professions, and by people engaged in connected occupations ,

(*b*) What, in the light of the foregoing, should be the proper current levels of remuneration of such doctors and dentists by the National Health Service ,

(*c*) Whether, and if so what, arrangements should be made to keep that remuneration under review , and to make recommendations

He could not fix a date by which the commission must report but he would certainly urge the chairman to proceed without delay

Mr John Rankin Is the Prime Minister aware that a B M A spokesman quoted in the press said that his reference to an interim adjustment is extremely obscure, and that it might mean any of a number of things, some of which would be entirely unacceptable ? Will the right hon Gentleman not make his attitude on the interim adjustment clear beyond a peradventure, or does he wish to give the tough boys in the B M A the ammunition necessary to destroy the Health Service ? The Prime Minister The sentence which I put into that letter means exactly what it says, and I do not wish to make any interpretation of it this afternoon At the same time, we are always in touch with the leading members of the profession, and either my right hon Friend or I will be very willing to make any further explanation at an appropriate moment

Mr Frank Beswick Is the Prime Minister aware that if, as the result of any uncertainty as to the meaning of the phrase "interim adjustment," any damage is done to the Health Service the people of this country will not forgive him ? Can he say why he cannot make it quite clear, both to allay apprehension on the part of doctors and also in fairness to those who may be invited to serve on this commission, that the commission is not now intended, as was originally the case, simply to dodge the issue, and does not preclude any interim negotiations upon salary-scales ? The Prime Minister The hon Member is very fond of making statements for which he has very little ground He prefers to rely rather upon innuendo than fact The commission was never intended for the purpose of dodging this issue Members on both sides of the House know the very difficult circumstances that surround some of these problems I am convinced that the commission will be able to act rapidly and effectively, and I am very hopeful that we shall reach a good point of view between all concerned in this matter

Dr Edith Summerskill Will not the Prime Minister say whether the terms of reference which he has mentioned will enable the commission to take into account the conversations conducted at the inception of the service between the Government and the doctors ? Further, will he again consider interpreting this phrase, because the attitude of the profession during the next few months may be guided by what he says now ? The Prime Minister On the first point raised by the right hon Lady I have not the record of these conversations with me at the moment Therefore, if she pressed me upon the matter, I should have to ask for notice I think it would be a matter for the commission itself to decide With regard to the right hon Lady's second point, I should prefer to leave the matter as it is at the moment I feel quite certain that we shall be able to make good progress in this affair

Mr Marcus Lipton asked the Prime Minister what communications he had received from medical organisations since his announcement of a Royal Commission on doctors' pay The Prime Minister replied I have received a letter from the Negotiating Committee of the medical profession, which has been published together with a copy of my reply Mr Lipton Is the Prime Minister aware that if he has another look at his reply he will see that the English is bad and the meaning obscure ? Will he say why he is so curiously unwilling to say whether this proposed interim adjustment may also apply to general practitioners ? The Prime Minister I am sorry about the English I am always ready to take advice from a very expert source I think the best thing I can do is to try to get the commission started, and I hope, with great confidence, that we shall be able to clear up the other issues as we go along

Mr E G Fletcher . Will not the Prime Minister agree that, whatever may be the case for a Royal Commission to examine the overall question of doctors' pay, there is a strong case for some immediate interim adjustment of doctors' remuneration, and will he acknowledge that and remove all the misunderstanding by making his position clear ? The Prime Minister Yes, Sir For that reason, I made reference to it in my letter

Mr Arthur Blenkinsop Will not the Prime Minister agree that, as he has made this specific reference in his letter to the British Medical Association, it is highly desirable that he should clarify it so that further dispute may be avoided ? The Prime Minister No, Sir I think that all this will move along satisfactorily The first thing to do is to get the commission appointed, which I am very hopeful will be quite soon What I have said in answer to supplementary questions has made it quite clear that my right hon Friend or I are very ready to take up these further questions with the Negotiating Committee

Mr G S Lindgren In view of the Prime Minister s intervention in this industrial dispute, will he also recommend to industry generally that it should give an interim award on outstanding pay-claims ?

Lung Cancer and Smoking

Speaking on the *motion for the adjournment* on March 1, Mr Marcus Lipton said that there was now statistically an incontrovertible association between cigarette smoking and lung cancer and asked the Government what they were doing to let the people know about this disturbing fact He realised that in raising this matter he was confronted with formidable difficulties £880 million a year was spent on tobacco Out of every £1 spent in the shops, 2*s* 6*d* was spent on tobacco and each adult incurred an average expenditure of 9*s* 4*d* a week Four million places were licensed for its sale, and the yield from duty produced £668 million in the last financial year, a record figure

Mr Lipton went on to recapitulate Ministerial pronouncements on the subject from Feb 12, 1954—"I accept the Committee's view that the statistical evidence points to smoking as a factor in lung cancer"—to the latest of Feb 25, 1957—"I propose to ensure that the public are kept informed of all relevant information as and when it becomes available" So far the Minister of Health had refused to accept the advice of his Standing Advisory Medical Committee that effective steps should be taken to make the facts known to the public and to counteract propaganda in favour of smoking Mr Lipton thought that it would be a grave dereliction of responsibility on the part of the Minister and the present Government if they deliberately continued to blind themselves to the seriousness of the situation and refused to take further action immediately He asked the Government not to shelter behind a stale and outworn formula but to do the job for which the Ministry of Health was appointed and paid—to protect and improve the health of the people

Mr Richard Fort, a lay member of the Medical Research Council, suggested that Mr Lipton had seemed more concerned with scoring cheap points off the tobacco companies and the Government than with considering one of the more complicated medical problems of our time He had failed to emphasise that the kind of work needed to find out the reasons for the statistical facts was very complicated and difficult scientific work Three points on which much more work was needed were (1) statistical analysis , (2) the effect on animals of the products from burning tobacco , and (3) the complex problems connected with smoking, air-pollution, chronic bronchitis, and lung cancer

Mr J K Vaughan-Morgan, parliamentary secretary to the Ministry of Health, said that the Government had *not hesitated to announce to the public any discovery* as and when it became available But though we must give full publicity to the knowledge which was *available,* we must not indulge in any form of sensationalism Carefully controlled inquiries had shown statistically that smokers had a significantly higher mortality-rate from lung cancer than have non-smokers The figure increased in direct proportion to the amount smoked, until among life-long heavy smokers, who may be defined as those smoking about 25 cigarettes a day, it appeared that about one in ten can be expected to die of lung cancer before the age of 75 Among heavy and continuous smokers of cigarettes—that is, those smoking substantially more than 25 a day—the death-rate from lung cancer was about *forty* times that among non-smokers The rates among pipe-smokers for the same amount of tobacco smoked were less than among cigarette-smokers Those who had given up smoking had significantly lower rates than those who had continued to smoke

There were many ways of interpreting the statistical evidence and it was difficult to reduce the evidence to average figures, but without doubt these findings constituted prima-facie statistical evidence that smoking carried a risk of lung cancer in human beings But we must view this mortality-rate and these risks with a due sense of proportion Of *a total of 518,000 deaths* in England and Wales in 1955, 17,000 were due to lung cancer out of a total of 91,000 for all *forms of cancer* That 17,000 compared with 28,000 *for* bronchitis and 70,000 for coronary disease and angina, apart from other forms of heart-disease Lung cancer was not our only problem, nor must it be our only preoccupation, nor should we give it any more priority than the figures justify *Nevertheless, it was undoubtedly the case that* the lung cancer figures continued to show a steady *increase, which had varied from 5 7 to 8 2%* per annum over the past five years

The Medical Research Council was engaged in research on the *relationship* between smoking and *lung* cancer, the long-term aim being to identify those constituents of tobacco smoke which might be active in producing cancer There had recently been built a laboratory at Exeter *for fundamental* work on the chemical analysis of *tobacco,* which was *the first fruits of the grant of a* quarter of a million *pounds* from the *tobacco* companies of this country Research was also going on in hospitals and universities all over the country

The Medical Research Council was currently reviewing the existing evidence, and its considered views should be available before long The Government would *give* those views their full and urgent consideration and he reiterated the pledge that the public *would be informed of all* the evidence *as* it becomes available *A pamphlet,* lately issued by the Ministry of Education, gave considered and helpful advice on the subject It was the firm intention of the Government to reveal the truth as it came to light, but we must avoid *any* unnecessary *sensationalism on this very difficult subject*

During much of the debate about half a dozen members were present

Paying for an Ambulance

On March 1 Sir FRANK MARKHAM moved the second reading of the National Health Service (Amendment) Bill, a measure which is more circumscribed than its title suggests The Bill gives effect to a recommendation of the Guillebaud Committee by permitting local authorities *to provide ambulances on a repayment* basis for purposes outside the National Health Service Act The purposes which the Guillebaud Committee had chiefly in mind were large public gatherings, such as race meetings or football matches The promoters are willing to pay the *local authorities for providing* an ambulance service, but at present the local authorities are not able to provide it Sir Frank gave an assurance that it was not the intention that this Bill should be the thin end of the wedge for making other payments for ambulance services *necessary* Mr VAUGHAN-MORGAN speaking for the Government at the end of the debate reiterated this assurance The measure, *he added* would permit the local authorities to provide a stand by service, at present strictly speaking, they could provide an ambulance only *after the event* He thought that the proposal might *also* be useful to some industrial undertakings, such as the National Coal Board, who had by law *to* provide an ambulance service for their employe-

The Bill was read a second time

QUESTION TIME

Remuneration of Junior Hospital Staff

Mr A BLENKINSOP asked the Minister of Health whether he would reopen negotiations with the medical profession for an interim settlement of their claim, pending the full review to *be undertaken by a Royal Commission* —Mr DENNIS VOSPER *replied* I am glad to be able to say that the Government are prepared immediately to recommend the management side of the appropriate Whitley Council to offer to negotiate an interim increase in the remuneration of hospital medical and dental staff up to and including the grade of senior registrar

Mr BLENKINSOP Does not the Minister recognise that his answer is merely a stonewalling answer ? When will he give us some information with regard to the interim negotiations in respect of general practitioners ?—Mr VOSPER It is not quite a stonewalling answer, because it relates to the Government's decision to offer to negotiate immediately for junior hospital doctors On that question I am still awaiting a reply from the Negotiating Committee

Cost of Prescriptions

Mr BLENKINSOP asked the Minister the average cost per prescription under the National Health Service for the month *of December, 1956,* and how this compares with the average cost in December, 1955 —Mr VOSPER *replied Approximately 5s 6½d,* which is about 11*d* more than in December, 1955

Mr BLENKINSOP Does the Minister realise that there has been a serious further increase in the cost per prescription since the new charges were imposed ? *Does not that show the very grave danger of the advice to doctors to prescribe larger* quantities per prescription ?—Mr VOSPER A great part of this increase occurred before the new prescription charge was introduced and it was also due in part to the increased chemists' remuneration and the release of new drugs, such as cortisone Only in part was it due to the new prescription charge As far as that is concerned, I should like to see the results for February and March before coming to a definite conclusion

Mental Patients

Dr A D D BROUGHTON asked the Minister of Pensions and National Insurance the number of patients in mental hospitals in England and Wales who, by reason of having been given a prison sentence before being certified as of unsound *mind, are not eligible for National Insurance* benefit —Mr J A BOYD CARPENTER There are about 200 mental patients who were certified while undergoing a prison sentence which has not yet expired I have no figures for the number detained under section 7 of the Criminal Lunatics Act, 1884 Under *decisions of the National Insurance commissioner* persons in both these categories are at present disqualified from receipt *of National Insurance benefits* Dr BROUGHTON Does not the Minister agree that these unfortunate people are harshly treated in respect of National Insurance benefits ? Is he *aware that if mental disorder had been recognised* and these people *certified before* court proceedings, they would not *suffer* the penalty of losing their National Insurance benefit including even the taking away of tobacco tokens from old age pensioners ? Will he be good enough to look into the matter *and consider the possibility of amending the* law ?—Mr BOYD CARPENTER I am not without sympathy for the hon Member's point of view, which I believe is shared by a number of people who have studied the subject I must, however await the Royal Commission's report which may affect the underlying *law,* but *I have in* mind, *when that report* is received, to refer this matter to my National Insurance advisory committee

Mr L D L DU CANN asked the Chancellor of the Exchequer why retirement pensioner patients in mental hospitals who would otherwise be entitled to tobacco tokens are deprived of them —Mr ENOCH POWELL replied Retirement pensioners are by statute entitled to tobacco tokens only if they receive their pension by means of weekly orders Their entitlement ceases if their order books are withdrawn, as happens when *the hospital concerned draws the pensions in bulk*

Anthrax Committee of Inquiry

Mr IAIN MACLEOD Minister of Labour, has announced the *appointment of a committee to consider*

the existing legal provisions concerning the importation of goods infected or likely to be infected with anthrax and the [illegible] to be taken in connection with such imported goods for the protection of the health of persons

The last full scale inquiry into the question of precautions against anthrax was made forty years ago

Blind Workers

The annual maximum grant to local authorities towards the cost of the provision of employment facilities for approved blind workers will be increased from £100 to £150 per worker from April 1 in view of the increase in costs

Research in Delinquency and Recidivism

A total of £10,934 has been paid by the Home Office, under section 77 of the Criminal Justice Act 1948, to assist research on the causes of delinquency and the treatment of offenders, and a further £1000 is awaiting payment In addition £2488 has been spent by the Social Survey as an allied service on behalf of the Home Office for research on these subjects

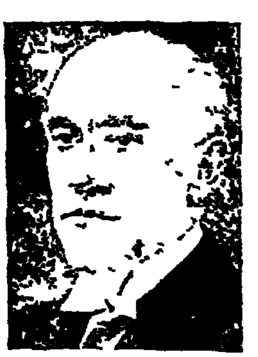
Obituary

HUGH STANNUS STANNUS

C B E , M D Ph D Lond , F R C P , D T M & H

By the death of Hugh Stannus on Feb 27 tropical medicine has lost one of its oldest advocates, who was in many ways a pioneer

He was born in 1877, the only son of Prof Hugh Hutton Stannus, F R I B A Educated privately, he studied medicine at St Thomas's Hospital where he qualified in 1901 After holding house-appointments there he was appointed resident surgeon to the Hertford British Hospital in Paris There he learned to speak fluent idiomatic French and attended the clinics of Poirier and Babinski



In 1905 he was appointed medical officer to the King's African Rifles in British Central Africa and later was posted to Nyasaland as medical officer with headquarters in Zomba He found himself much at home in primitive Africa with avenues of inquiry and research enticing him on every hand, and in the years before the outbreak of the first world war he made an intense study of anthropology and ethnology on the many interesting and primitive tribes of Nyasaland His chief work was a monograph on the Wa-Yao people, which was well illustrated He also published papers on pellagra, trypanosomiasis, blackwater fever, and piroplasmosis Indeed the seeds of all his later work on the nutritional and venereal diseases were sown during his early tropical service He was one of the first if not the first, to draw attention to pellagra in Central Africa, as he saw it in Zomba prison in 1910 He pointed out the symmetry of the rash and disposed of the maize theory" of its causation In 1911 he took his M D and was awarded the university gold medal

From 1914 to 1918 he served as principal medical officer of the Nyasa-Rhodesian Forces fighting von Lettow in Tanganyika On his return to England after the war he was offered the post of director of medical services of the newly constituted Tanganyika Territory but his health had been undermined and he was advised to refuse it He therefore determined to make a fresh start in England and after a year s postgraduate study he settled in consultant practice in London He became physician to the French Hospital in Soho, where he remained till he retired in 1943 He was also associated with the old Hospital for Tropical Diseases at Endsleigh Gardens, and he was medical adviser to the Board of Inland Revenue and the High Commissioner for Rhodesia, and consultant to the Ministry of Pensions and Somerset House He was a sectional editor of the *Tropical Diseases Bulletin* He was elected F R C P in 1931

In 1937 Stannus became interested in lymphogranuloma inguinale He was the first to describe a case of this infection acquired in England and his most important book, *A Sixth Venereal Disease*, was published at this time In 1937 he returned to the age-old question of the relationship of yaws to syphilis During the late war he was consultant to the Ministry of Health on diseases of malnutrition and with Prof V Sydenstricker and Dr R Brunel Hawes started the rapid nutritional surveys He also became interested in the ocular manifestations of ariboflavinosis which he summarised in his Lumleian lectures to the Royal College of Physicians in 1944 In 1942 he propounded a new theory on the ætiology of tropical sprue.

He was a chevalier of the Legion of Honour and of the Ordre de la Santé Publique , he held the Médaille de la Reconnaissance Française In 1948 he was awarded the Treacher Collins prize and last year he was appointed C B E He had also been a master of the Founders' Guild of London, and his interest in the history of the guild and of London perhaps led him to take up genealogy as a hobby R B H relates how

to this he brought a passion for accuracy He would not accept any statement on family tradition however plausible when tracing a family unless he found documentary evidence confirming it This led him on to searching hundreds of wills in Somerset House and ancient birth registers in many towns and villages as well as writing to and travelling to meet anyone who might give him any clue in his search. In one instance he suspected a man whose parentage was in doubt to be a natural son of George IV He got into correspondence with a descendant in America who possessed a portrait of this man and obtained a photograph of this picture Armed with this he searched until he obtained an engraving of George IV at the same age and in a similar posture to compare them. His genealogies must be remarkable not only for their accuracy but even more so because they included notes of events in the lives of those he recorded He took great pleasure in the discussion of fresh ideas and puzzling cases, and his death will be a real loss to his many friends who delighted in his conversation

P M -B writes

Stannus was well liked and especially respected by the younger members of the profession for his ever helpful attitude. His was a distinctive personality, with rather a hesitant speech adorned with little mannerisms He would roll his eyes upwards, on being addressed, as if in alarm, break out into a smile, with a chuckle and ending in a kind of sigh He was slightly built with a forward stoop, and a peculiar swinging gait He always looked half famished, but he was tough indeed, because he survived many years of ill health In habit of mind he was critical , he could be argumentative and never took facts for granted

G P writes

Hugh Stannus's scholarly distinctions carried his reputation beyond these islands but of this quiet humble man more could be written Those nearest to his professional life on the staffs of his hospitals and those who served under, and with, him on committees will never forget his charm and gentleness in his dealings alike with patients and colleagues and how, diffident as he always was in the defence of his own interests, in support of a colleague on a cause which he felt to be just he would, in a flash, become a raging lion

In his younger days he was athletic and I well remember him, not so many years ago, swimming vigorously up and down the baths on a Saturday morning The last decade of his life was crippled by rheumatism, but this in no way diminished his cheerfulness and youthful enthusiasm Although a consulting physician in a circumscribed field, his interest in progress in all branches of medicine and surgery was intense, and he enriched any discussion in which he took an always humble part

JAMES BEAVER MENNELL

M.A , M D Camb

Dr J B Mennell consulting physician in physical medicine to St Thomas's Hospital London, who died at his home at Liss, Hampshire on March 2, at the age of 77, pioneered the use of physical methods for reablement after fractures and other injuries

From St Paul's School he went to Pembroke College Cambridge, and thence to St Thomas's Hospital, from which he qualified in 1908 For the next twenty-seven years he worked without interruption at St Thomas's His earliest appointments there included those of casualty assistant and house-surgeon, and even by then he had recognised the serious gap in the treatment of injuries after the initial phase P B writes

To summarise Dr Mennell's professional activities by saying that his life was devoted to massage, manipulations, and remedial exercises would be a gross inaccuracy and an injustice He was essentially a man of great clinical acumen who broke away from tradition, and with much courage and perseverance set out to apply physical methods to therapeutic ends His interest in the field which must ever commemorate his name began when he was still a student at St Thomas's Hospital, and observed that the after treatment of fractures was virtually non existent After qualification, his concern with after treatment of fractures and injuries in outpatients was rekindled, and very soon after he was appointed in the then "department of physical exercise" an unofficial clinic for fractures and trauma evolved under him

As a pupil of Lucas Championnière he employed initially the methods of his teacher, but he soon modified these and developed his many techniques aimed at early restoration of function Many of these, considered unorthodox at the time, have now become a matter of routine, and in this sense can Dr Mennell be looked upon as having laid the foundation of rehabilitation

J B, as he was affectionately called by his colleagues, was a dedicated man and never spared himself despite the indifferent health which forced him to retire from hospital work before his time in 1935

His writing his lecturing, and his starring in a film which he directed himself bear witness to his industry after retirement, and account for his deserved reputation as a teacher and a clinician, not only in this country and the Commonwealth but on the Continent and in America

Much of his energy was spent in the interest of physiotherapists, and the school of physiotherapy at St Thomas's Hospital owes much of its success to his encouragement and enthusiasm His continued and devoted concern with physiotherapy earned him the chairmanship of the council of the Chartered Society of Physiotherapy after retirement, while at St Thomas's Hospital his memory was kept alive in a bursary for teachers of physiotherapy, which bears his name At the time of his death, he was still president of the Old Physiotherapy Students' Association

Dr Mennell had served as president of the section of physical medicine of the Royal Society of Medicine, and as a member of the council of the British Association of Physical Medicine His books included *Physical Treatment by Movement, Manipulation, and Massage*, *Backache*, and *The Science and Art of Joint Manipulation*

He is survived by his widow and three sons

WILLIAM STOBIE

O B E, M A Oxfd, M D Edin, F R C P, J P

Dr William Stobie, for long consultant for tuberculosis to Oxford and to Oxfordshire and a past mayor of the city, died at his home at Cumnor on March 2 at the age of 70

He was born in Edinburgh and was educated there at George Watson's College and the university He graduated M B in 1908 and the following year he went to Oxford to become Osler's house-physician at the Radcliffe Infirmary Later he held other resident appointments under the late Dr A G Gibson and at the Eye Hospital His knowledge and interest in general medicine had thus been firmly established and discerningly stimulated before he began to specialise in diseases of the chest His work was given this direction by Osler's foundation of the Oxfordshire Association for the Prevention of Tuberculosis Stobie was chosen as its first medical officer, and to begin with he visited the outlying clinics by motor bicycle, and a colleague, recalling Stobie's still earlier experience as an assistant on horseback and push-bike, affirmed that "there is no doubt that he felt safer on these more primitive modes of progression than in his later motor-cars"

During the 1914–18 war Stobie did not lose touch with Oxford He served as medical officer with the Oxford and Bucks Light Infantry For his work he was twice mentioned in despatches and appointed O B E After his return to civilian life he took the M D in 1921, and five years later he was appointed physician to the Osler pavilion for diseases of the chest at the Radcliffe Infirmary In 1934 he became consultant in tuberculosis to the city and the county The same year he was elected F R C P and in 1938 the university conferred on him the degree of M A When the National Health Service was started in 1948 he became consultant in diseases of the chest to the United Oxford Hospitals and clinical lecturer in the university He retired from these posts in 1952

In the midst of these professional responsibilities Stobie did not neglect his responsibilities as a citizen In 1930 he had become an alderman and the following year he was elected mayor of the city In 1932 he became a justice of the peace, and in 1951 he was elected chairman of the Oxford bench

A colleague writes

Few men can have had more friends than William Stobie—friends to whom he gladly gave more than most of them were able to give him in return In thinking about his unusually full life, one is at first confused by the variety of his many-sided activities We remember him first and foremost as "a good doctor" who always put the patient first—a memorial that many of us would deem sufficient in itself His chief professional work lay in the treatment and prevention of tuberculosis, but he never lost his interest and enthusiasm in general medicine and in medicine related to ophthalmology But Stobie's boundless mental and physical energy led him into many other branches of service to his fellow men, both in war and peace We think of him as mayor of Oxford as refereeing rugby football matches, as chairman of the bench as a rose grower, as a formidable expert on committee procedure, and an outspoken critic, yet the kindliest and most hospitable of men We think of him as a small square man always friendly, with a tremendous laugh on the appropriate occasion, and always busily employed in doing something to help someone else We remember him with gratitude and affection

In 1914 Dr Stobie married Miss Irene Taylor of Shelsley Walsh, Worcestershire She survives him with their two sons and their daughter

HERBERT CALDER ELDER

M B Edin, M R C P E, D P H

Dr H C Elder, late chief tuberculosis officer of Edinburgh, died on Feb 23 at the age of 68 He was educated at Harris Academy, Dundee, and at the Universities of St Andrews and Edinburgh, graduating M B Edin in 1917 His appointment as house-physician to Sir Robert Philip at the Edinburgh Royal Infirmary was the origin of his life-long interest in and enthusiasm for tuberculosis A year after his appointment in 1919 as assistant tuberculosis officer to the corporation of Edinburgh, he was elected M R C P E He was promoted to the post of chief tuberculosis officer after nine years' service, and he held this appointment until he retired in 1953

At an early stage in his career he developed a special interest in the diagnostic procedures applicable to diseases of the chest, and he became one of the pioneers of bronchography in this country Recognition of his capabilities as a clinician, and of his extensive knowledge of tuberculosis, led to his appointment as lecturer in this subject to the school of medicine of the Royal Colleges of Edinburgh in 1930 He resigned from this post in 1939 at the outbreak of war

A colleague writes

Dr Elder's gifts of intense concentration and grasp of essential detail became evident in the skill with which he solved any pertinent problem and in his mastery of the wide variety of subjects in which he was interested He was an accomplished musician with a profound regard for the [illegible] He [illegible] a fluent French linguist and, in his youth, a crack golfer He tried to cloak a shy and retiring disposition with a brusqueness which was often misinterpreted But his patients, whose interests and welfare were always his concern, were usually quick to recognise that his strictness as a disciplinarian was equalled by his warm humanity and innate kindliness

Dr Elder leaves a widow

Notes and News

WOMEN CANDIDATES ONLY?

FOR some months doctors and patients in Edinburgh have been discussing whether a consultant vacancy in the Southern hospital group of the city should be restricted to women andidates The regional hospital board proposes to combine wo part time appointments—one previously held by a woman at the Bruntsfield and Elsie Inglis Hospitals, the other held by a man at the Deaconess and Longmore Hospitals—to form a new post of consultant to the whole hospital group The hospital management committee think that in open competition a woman candidate might not be appointed to this combined post, and they are disturbed because there would then be no woman medical specialist in the whole South-Eastern region, and because the change would break the tradition of the Bruntsfield and Elsie Inglis Hospitals, which have been staffed by women since their foundation over fifty years ago The Secretary of State for Scotland has also received protests from the Edinburgh local medical committee and executive council and the Medical Women's Federation, and a petition signed by 20,000 people He has announced, nevertheless, that he has decided not to interfere with the discretion of the regional hospital board He adds that the board "have emphasised to him that should a woman candidate prove herself worthy in open competition she would be appointed to the combined post with their fullest confidence"

THE DENTAL SCENE

THE annual clinical meeting of the Guy's Hospital Dental School was held last Saturday Besides the clinical cases there were numerous table demonstrations, which are always useful guides to new developments and methods in operative dental surgery—as well as serving to recall the various small, but often important points which tend to be forgotten in the press of routine dental practice The ordinary dental engine still appears to be the best instrument for cavity preparation, in spite of the rival claims of air propelled abrasive dust and ultrasonic drills The emphasis is now on high speed engines, with diamond or carbide burs, rotating at five or six times the speed formerly used, and Mr W A Vale showed what could be accomplished with such a machine in the rapid and painless preparation of cavities At the moment the limitations of this method are those imposed by the ability of the handpiece to stand continuous high-speed running

The dental students are now encouraged to do original work, and the results of several ingenious and promising lines of research were on view A problem that is still unsolved is whether the dentinal tubules contain nerve fibrils J W Fernhead,[1] of the London Hospital, claims to have demonstrated their presence, but Guy's remains sceptical and holds to the view that pain during cavity preparation is caused by changes in hydrostatic pressure transmitted through the tubules to the pulp Work is still in progress and perhaps by next year the answer will be known for certain

In a lecture which he called Rock Around the Gas Room, Dr W S McConnell contrasted—often with masterly understatement—the hospital gas room of today with that of twenty five years ago Despite the attractions of cyclopropane, nitrous oxide and oxygen remains the standard anæsthetic for all dental patients over 4 years of age, but adjuvants and premedication are used freely when there are any possibilities of anæsthetic difficulties Ethyl chloride, once given as a routine to children, is no longer used at all instead divinyl ether, by itself, is given to children under 4, and for induction to children up to 6 Discussing the numerous drugs from which the anæsthetist can now choose, Dr McConnell emphasised the value of intravenous pethidine for the apprehensive patient He also remarked that in the ordinarily recommended dosages the barbiturates, methylpentynol, chlorpromazine, and an inert substance had all proved equally effective—or ineffective—in reducing apprehension in the dental chair

A lecture by Prof M A Rushton was illustrated by radiographs and photographs of some of the more unusual dental cases referred to him during the year by dental practitioners Although some may regard oral pathology as one of the more esoteric branches of dental practice the size of his audience showed the great interest in this subject Afterwards he introduced a short teaching film on Biopsy Techniques made by Mr B E D Cooke—a valuable film not only for students but also for any dental surgeons who wish to ensure that their biopsy specimens will have the greatest value for the pathologist

HOME-MADE

A REVIEWER may occasionally allow himself the pleasure of commenting on the excellence of the production of a work, and it gives particular pleasure to commend that of Dr J Gibson's [1] pamphlet on St Lawrence's Hospital, Caterham, for it was set up and printed by the patients

The Caterham Metropolitan Asylum (as the hospital was originally called), and its twin hospital at Leavesden, opened in 1870 to "such harmless persons of the chronic or imbecile class as could lawfully be detained in a workhouse" The hospitals owe their existence to the Metropolitan Poor Act, which was so largely inspired by Florence Nightingale Under this act, the board of what was called ("with a reckless disregard of initials," says Dr Gibson in his pleasing account) the Metropolitan Asylum District decided to build the two hospitals to an identical design Many buildings have been added since, even in 1875 there was a swimming bath

Over 300 patients were admitted in the first year, and by 1877 the numbers had reached about 2000 In the early years most patients were psychotic, but now, of the total 2200, 2000 are mentally defective They include children over the age of 5 years, some of whom are admitted only for short periods during which their parents cannot look after them Most of the patients have severe degrees of deficiency, but useful occupation or instruction is found for many of them The illustrations include photographs of a modernised ward, a classroom, and the new printing shop (provided by the Nuffield Provincial Hospitals Trust) where the pamphlet was produced

HELP FOR DISABLED PEOPLE

A SERIES of articles has been appearing in the *Social Service Quarterly* in recent years on what is being done to help disabled people This series has proved very popular, and the first fifteen articles have now been published in book form [2]

As the late Dame Georgiana Buller pointed out in her introduction, there are few tasks—if indeed any—which call for complete physical integrity The remaining essays are concerned with what can be done to train and use the able remnant of the maimed person Some cover specific disabilities (such as deafness) or specific groups (such as school leavers), others discuss organisations at world and at county level There is much useful factual information, including an enlightening account of many ingenious but simple devices (such as a fixed nailbrush for the one handed man) which can make life at home or at work much easier

The picture this booklet presents of what can be done is as encouraging as it is stimulating To quote Dame Georgiana Buller again, "Pity is a cheap emotion and a negative one True sympathy—feeling with—demands the effort of comprehension and is productive of results"

University of Cambridge

On Feb 23 the degree of M B was conferred by proxy on R H Lavelle

Royal College of Surgeons of England

Mr A Lawrence Abel will deliver the Bradshaw lecture on Thursday, March 14, at 5 P M, at the college, Lincoln's Inn Fields, London, W C 2 He is to speak on diseases of the large intestine

Victor Horsley Lecture

Sir Geoffrey Jefferson, F R S, will deliver this lecture at the house of the British Medical Association, Tavistock Square, London, W C 1, on Friday, April 12, at 5 30 P M This is the centenary of Horsley's birth and Sir Geoffrey is to speak on his life and work

Society for Social Medicine

This new society will hold its first scientific meeting in Birmingham from Sept 24 to 26 The hon secretary is Dr Alice Stewart Department of Social Medicine, 8, Keble Road, Oxford

Chest Diseases and the Family Doctor

A weekend course on this subject for general practitioners is to be held at Norwich on April 13 and 14 Further particulars can be had from the Tuberculosis Educational Institute, Tavistock House North, London, W C 1

Blindness in Mental Deficiency

A meeting on this subject will be held at the Fountain Hospital, Tooting Grove, London S W 17, on Wednesday, March 13, at 5 30 P M The speakers will be Prof Arnold Sorsby, Dr L Crome, and Dr C E Williams

Humane Technique in the Laboratory

The Universities Federation for Animal Welfare is holding a symposium on this subject at Birkbeck College, Malet Street, London, W C 1, on Wednesday, May 8, at 9 45 A M, under the chairmanship of Prof P B Medawar, F R S

Institute of Diseases of the Chest, London

There will be a discussion for general practitioners at this institute (in the grounds of the Brompton Hospital, S W 3) on Tuesday, April 9, at 2 30 P M, on hay fever and asthma Further information may be had from the secretary of the institute

British Association of Physical Medicine

The annual meeting of this association will be held on April 5 and 6 at the Middlesex Hospital, London, W 1 The programme includes a discussion on poliomyelitis, when the opening speakers will be Dr R W Gilliatt, Mr D M Brooks, Dr B E W Mace, and Squadron Leader C B Wynn Parry Further particulars may be had from the association, 45, Lincoln's Inn Fields, W C 2

National Association for Mental Health

The subject of the annual conference of this association, which is to be held at Church House, Westminster, London, S W 1, on April 11 and 12, is to be The Maladjusted Child—the Underwood report and after The speakers will include Dr Kenneth Soddy, Dr John Bowlby, and Dr Mildred Creak Further particulars may be had from the association, 39, Queen Anne Street, W 1

Sixteen specialists from nine countries are visiting London hospitals to see demonstrations in anæsthesia They are taking part in a course arranged by the British Council and the Faculty of Anæsthetists of the Royal College of Surgeons of England

W D W BROOKS
CBE, DM Oxfd, FRCP
PHYSICIAN TO ST MARY'S HOSPITAL AND TO BROMPTON HOSPITAL, LONDON

> "The preservation of health is, without doubt, of all blessings in this life the first and fundamental one"
>
> DESCARTES (1637)

IT is of paramount importance in Darwin's evolutionary theory that a species must adapt itself to its surroundings or perish, and this law is well illustrated by the relationships which may be established between a host and its parasites We know that when a parasitic micro-organism colonises a new host one of three things may happen There may be adaptation by both, producing a carrier-state, or adaptation may fail because, in one way or another, the host destroys the parasites, or, after a Pyrrhic victory represented by a fatal illness for the host, both he and his parasites die together Each of the last two possibilities represents a failure by the micro-organism to adapt itself to its environment, unless in either event the struggle is sufficiently protracted, and the circumstances propitious enough, to permit transference to another host before the micro-organism dies Since a majority of mankind is infected with tubercle bacilli, and since it would be vain, as yet, to hope to suppress all sources of tuberculous infection quickly, even in those parts of the world healthiest in this respect, the effective prevention of the disease in man must rest essentially upon a proper understanding of these principles Clearly, any measure which will reduce the hazard of infection is of supreme value, but, when the course and outcome of the battle of mankind versus tubercle bacilli are envisaged, it would not be realistic to fail to give first place to the statistically much more significant problems of the infected Paradoxically, it is here that our knowledge, and its practical application, are relatively deficient

The Infected

As is the case with many other host parasite relationships, the carrier state between man and tubercle bacilli is much the most common consequence of infection It is usually achieved following primary infection, but is also quite often seen in post primary and in adult-type disease All of these tuberculous states are examples of unstable equilibrium, and adaptation may fail at any time, but the reasons for this failure are very incompletely understood To put the same point into other words, we do not know at all accurately why primary infection is followed by progressive tuberculosis in one case but by healing in another Similarly, in post-primary and adult type disease, progression, remission, and relapse are not predictable with any certainty Furthermore, the part played by superinfection at any of these stages of tuberculosis is very imperfectly appreciated We do know that human beings vary in their biological response to infection, and in part at least this response is determined by constitution Thus, primary infection leads to progressive tuberculosis far more often in some relatively unexposed races, because the susceptible stock has not been removed as has happened in other races during centuries of exposure to infection A similar argument presumably also applies to individuals and their families Likewise, clinical observation shows that physical and mental fatigue, and certain diseases (some constitutional, others acquired), modify the course of tuberculous infection More important, however, is the effect of nutrition Wherever this has been studied, it has been shown that an inadequate food-supply is associated with enhanced tuberculosis morbidity and mortality, and that both these rates fall as food-supply is increased to an optimum level This is true irrespective of age and race and under widely differing climatic conditions For many years, fatigue, nutrition, and consecutive disease have been in some degree within human control and from this knowledge developed the basic therapy of tuberculosis

Finally, the age of the host is important Rich (1944) has summarised the position in adolescence thus "The sharp rise in mortality that follows the childhood period of relative safety is associated with the following circumstances

> (i) a progressive increase in the incidence of infection,
>
> (ii) apparently a specific adverse effect of the state of pubescence on resistance, and,
>
> (iii) the beginning of exposure to the stresses and strains associated with a struggle for existence and with childbearing"

That other less evident factors may be operative cannot be denied In infancy certainly, and possibly in old age, resistance to infection and to the progression of tuberculosis is relatively low

Primary Infection

For these reasons, in the early years of this century, the view was widely held that primary infection in childhood was a useful asset it rarely progressed to a serious degree, and the children developed some immunity which was thought to be of considerable benefit in adolescence and young adult life For the inhabitants of an English industrial city in the latter half of the 19th century, for example, it was in all probability an advantage to have thus acquired some immunity, since they were heavily exposed to infection for the rest of their lives in their homes and in the factories where they worked In much of the world today the epidemiological position is still the same, but in many countries, including our own, it has vastly improved in that exposure to repeated gross infection is uncommon, and the standard of living is high enough to secure for the vast majority a fair degree of natural resistance to tuberculosis which ensures their survival as they grow up Moreover, the risks of primary infection are in actual fact considerable, for dissemination may soon follow, or after a latent period which is often considerable the quiescent infection may flare up and progress Indeed, for these reasons, and from the results of many follow-up studies, it is now recognised that the prevalence of tuberculosis in any generation is determined during the early years of life (Dubos 1956) Thus, the mortality-rates from tuberculosis can be accounted for statistically by the assumption that every generation has the same pattern of mortality at various ages in other words, its level of mortality from this disease is determined early in life, and remains peculiar to it thereafter This epidemiological law is probably valid today for those countries which have a relatively low and falling tuberculosis mortality, and it emphasises that in these circumstances one of the most effective methods of prevention of tuberculosis is to attack the disease during infancy and childhood

Infants and young children as a rule experience their first infection without clinical or radiological evidence of disease, so that detection of the event depends upon serial tuberculin skin-testing, and, however true it may be that we still lack proper understanding of the scope, limitations, and value of this test, it remains our most sensitive diagnostic procedure Heaf (1956) has suggested that tuberculin testing should be done in the first, second, fifth, ninth, and twelfth years of life as a practical routine—ideally, of course, much more frequent testing is desirable—and that health visitors and nurses should be trained in this technique and use it, as in fact they do in Scandinavia The discovery of a positive tuberculin test will permit full investigation not only of the infected individual but also of the contacts, among whom—as Gedde Dahl (1952) and McDougall et al (1953) showed —there is a considerable probability of discovering an infectious person requiring treatment Furthermore, the epidemiological considerations outlined above lead logically also to the conclusion that recent primary infection, irrespective of apparent health or disease, is an indication for treatment with antimicrobial drugs What in this connection may be called chemoprophylaxis, in type and duration adapted to the particular features of each case, is already widely used in America, and has the advantage that, for the great majority, interference with the normal routine of life is unnecessary There would seem to be no reason why the same argument and management of the situation should not apply to primary infection acquired later in life If chemoprophylaxis is widely adopted and succeeds in its aim, the population of today which carries living virulent tubercle bacilli in the latent form—that is to say lives in a state of uneasy neutrality with its tuberculous parasites—will in time be replaced by a population in which these organisms have been largely destroyed by the combined effect of natural defence mechanisms and chemotherapy No one would belittle the theoretical and practical difficulties of such a programme, but until much more exact knowledge of the mechanism of antituberculous immunity is achieved—until we can as a practical procedure measure, and if necessary fortify, the state of immunological resistance of an infected individual—it is both logical and imperative to do the best we can to destroy the organism at a time when it is most accessible

---

* The Marc Daniels lecture for 1957, given to the Royal College of Physicians on Jan 15

Post-primary and Adult-type Disease

In much of the world, tuberculosis mortality was falling fast before the introduction of chemotherapy and surgical resection During the past twenty years, with increasing momentum, these two therapies have greatly improved prognosis in post-primary and adult-type disease, and have undoubtedly saved or greatly extended many thousands of lives in this country alone To estimate their significance in terms of preventive medicine is much more difficult, because usually, neither together nor singly, do they produce a bacteriological cure We may reasonably expect that for many years a considerable population in constant need of supervision lest relapse should occur will be with us, and it will be the larger because of the very success of the methods used

When we add to this the disturbing fact that drug-resistant forms of tubercle bacilli are isolated increasingly often, even after several different drugs have been used simultaneously in treatment, we are again brought back to the fundamental fact that, once it has been infected, it is the human body itself, through its own defence mechanisms, which determines the issue As has been said, little is known of these mechanisms

Vaccination of the Uninfected

Although for more than fifty years it has been known that the resistance of animals to tuberculosis can be raised with vaccines consisting of either dead or attenuated living bacilli, only one of very many attempts to produce immunity has so far proved of practical value in man B C G, today widely used among the previously uninfected, derives directly from the parent strain developed by Calmette and Guérin at the Pasteur Institute at the turn of the century, and an important disadvantage in its use arises from the inevitable divergence of the characteristics of its many descendants Thus, a method for its biological standardisation is much needed, and we also lack the means of measuring the level and duration of the immunity to which it gives rise Unfortunately, too, all forms of tuberculosis vaccine, including that prepared from vole tubercle bacilli, render the vaccinated person tuberculin positive to skin tests, and therefore eliminate our most sensitive diagnostic method—one which is of increasing value as the average age of primary infection rises All this would be insignificant if B C G or vole bacillus vaccine did provide complete, or even considerable, protection against tuberculosis, but it is certain that the degree of immunity they induce is of a moderate order and probably temporary Thus, there is no evidence that immunity acquired in this way can ever prevent infection or superinfection by virulent organisms There is, however, evidence (Medical Research Council 1956) that progression from infection to disease is retarded, so that acute forms of tuberculosis occur less often in the vaccinated The value of these vaccines in preventing the epidemiologically and socially much more important chronic pulmonary tuberculosis seems less certain (Daley loc cit) Some recent work by Strom (1955) in Sweden and Pasquier (1955) in Paris, using B C G and tubercle bacilli in which radioactive isotopes (^{32}P and ^{14}C respectively) were incorporated, is of importance in this respect They have shown that virulent bacilli injected into a previously vaccinated animal are not disseminated as quickly or widely as are the same organisms injected into a normal unvaccinated animal—proving that vaccination does retard the spread of infection They have also shown that the vaccinated animal can destroy injected bacilli more rapidly than can the unvaccinated animal. This method of investigation, using labelled B C G, has been repeated in man and has given the same result It is a very important method of research, and will probably be developed extensively

A review of the advantages and disadvantages of B C G suggests that in countries such as New Zealand Canada, the United States of America, Scandinavia, and our own, where the risk of infection is relatively small and the resistance of the native population relatively high, its use should be limited to certain groups These include those known to incur a considerable risk of infection, such as contacts (whatever their age), hospital workers, and seamen They also include, because of their known susceptibility, adolescents and young adults and immigrants of (for example) Irish and Negro stock On the other hand, in countries such as India, China and much of the Middle East, where the risk of infection is comparatively high, all uninfected persons would derive benefit from vaccination, and this also applies to immigrants and travellers who have occasion to go there for any appreciable length of time

The Prevention of Infection

The uncertain outcome of events after infection by tubercle bacilli clearly indicates that prevention of infection is the most important measure for the preservation of health To achieve this, it is necessary to discover and then eliminate sources of infection Much has been done in this respect in some parts of the world, little in others

Bovine Tuberculosis

Fifteen years ago in this country, Wilson (1942) estimated that infection with bovine tubercle bacilli was responsible for 1500–2000 deaths every year At that time there was evidence from the United States and Scandinavia that a policy of drastic eradication of bovine tuberculosis and pasteurisation of milk led to direct and rapid prevention of this type of tuberculosis in man The adoption of a somewhat comparable policy here has had similar results, and the disease is now very rare The prevalence of bovine tuberculosis probably varies widely in different parts of the world, and in many countries nothing is known of its extent

Human Sources of Infection

From person to person pulmonary tuberculosis is spread by droplets and dust The use of masks for those especially exposed to risk of infection (e g , nurses) and the training of infectious patients in the control of sputum and coughing, are sound preventive measures. The latter training is especially important, since for a variety of reasons it is impracticable, in this and in many other countries, to isolate every known infective patient until either cure or death results. In addition, when isolation is impossible, it should be remembered that infants, adolescents, and young adults are likely to be the most susceptible of those coming in contact with the patient, and therefore merit priority in any measures of prevention which may be practicable (Daniels et al 1948).

The proper treatment of patients, their rehabilitation, and the provision of financial assistance to them and their families are all important measures in preventing the spread of the disease to others. They are also much the most costly. Indeed, Benjamin (1955) has estimated that to provide for the treatment of tuberculosis in India on the scale commensurate with its known extent would cost more than three times the sum now available for the entire public health and medical relief services of that country. The authorities there are wisely concentrating at first on more directly effective and less expensive preventive measures. None the less, in the prevention of the disease, therapy for known cases is not to be despised. Indeed, it is essential.

The major problem, however, is the detection of infectious and potentially infectious cases before they have spread infection to others and then to treat these patients so that they become uninfectious. The traditional method of detection is to examine those who have clinical evidence of the disease, and it is an effective method if to clinical investigation bacteriological and radiological investigations are added. If the public were educated to expect these last two investigations as a matter of course when respiratory illness is suspected, examination of patients would become an even more useful preventive method than it is at present. This would imply the provision of better facilities for X-ray and bacteriological investigation on behalf of the general practitioner. Such facilities exist in this country, but they could be improved with advantage.

Similar methods of examination, when applied to contacts of known post-primary and pulmonary tuberculosis, also yield a considerable harvest of cases, and a proportion of these will be inapparent in the sense that there will be no clinical evidence of disease. Since in tuberculosis the interval from infection to disease varies, and may extend to two, three, or even more years, re-examination of contacts is very desirable.

Unsuspected cases of pulmonary tuberculosis are also often discovered if routine X-ray examination of the chest is used as a condition of employment and emigration. In these circumstances a problem in ethics may well develop, for the rights of the individual may conflict with the rights of population groups or of nations to protect their health. The level at which this conflict will arise—and, still more, that at which it will be settled—will largely depend on public opinion about the significance of tuberculosis. As a nation, we are today far less demanding in respect of examination to exclude tuberculosis than are several other Commonwealth countries or the United States.

A most important preventive measure for hospital workers and patients, and one used increasingly in the United States and Canada in the last decade, is the routine chest X-ray examination of *all* patients admitted to general hospitals. Those found to have radiological evidence of pulmonary tuberculosis may then be segregated in special wards for further investigation and treatment. This has been done in St Mary's Hospital for the past four years. The considerable extent of unsuspected tuberculosis and of other intrathoracic disease thus disclosed, as well as the benefit for hospital personnel, is being published elsewhere. There is little doubt that this procedure should be used in every general hospital in this country.

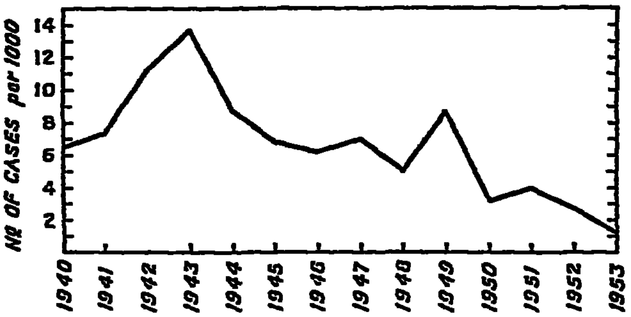

Fig 1—Incidence of pulmonary tuberculosis number per 1000 fluorographed Royal Navy, men new entry 1940–53

Miniature mass radiography (fluorography), made practicable by the work of D'Abreu (1936), has been widely adopted throughout the world as the least costly procedure for finding otherwise inapparent cases of pulmonary tuberculosis in various population-groups. It gives a much more accurate picture of the prevalence of the disease than any other method. For our purposes today, its epidemiological value may be illustrated by some experience in the Royal Navy, where it was first used and developed in this country—largely through the efforts of the late Sir Sheldon Dudley—and where it has become an annual event for every sailor.

Fig 1 shows the incidence of pulmonary tuberculosis (revealed by fluorography) in men newly entering the Royal Navy from 1940 to 1953. It thus shows the incidence of inapparent tuberculosis in these years in men, mostly young who had previously been physically examined, coming fresh from civilian life. A well-marked trend is evident indicating a decrease in incidence over the fourteen-year period. This tendency was twice interrupted—in the years 1941–43 and again in 1949. The first rise in incidence took place after civilian sanatoria and chest hospitals had been largely emptied of their patients and air-raids had imposed a "shelter life"—the interval being compatible with what is known of the usual incubation-period of the disease. The second rise, in 1949, correspondingly followed the worst phase in the shortage of beds for the treatment of pulmonary tuberculosis. At this time (1946–48) large numbers of infectious patients waited at home many months for treatment, thereby increasing the risk of infection for the general population. I know of no better or clearer illustration of the relationship between risk of infection and resultant disease.

The most important and easily understood index of the consequence of repeated fluorography upon the incidence of pulmonary tuberculosis in the Royal Navy is to be found in the attack-rate of the disease in those

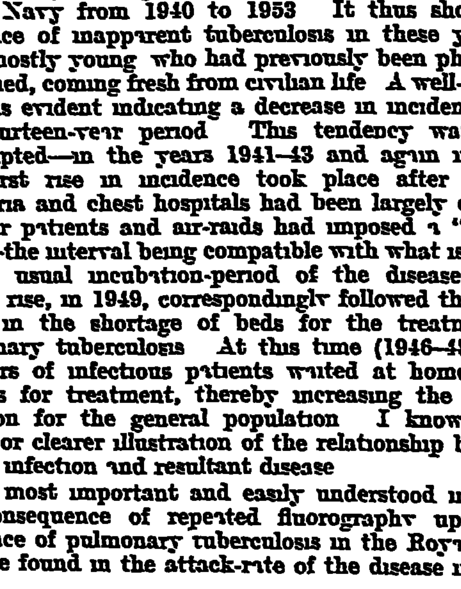

Fig 2—Incidence of pulmonary tuberculosis number of new cases per 1000 fluorographed, in those previously normal to fluorography Royal Navy, men. 1944–53

established personnel previously found to be normal to fluorography This is measured by the aggregate of the incidence of new cases disclosed by fluorography, and of new cases diagnosed through disease becoming clinically evident The latter had been shown by Dudley (1938) to have remained fairly constant at 2 per 1000 per annum for many years before the war It had fallen (Brooks and Frazer Roberts, unpublished) by 1945 to 1·1 per 1000 per annum, and in 1953 was 0 54 per 1000 The former incidence is shown in fig 2 and covers the period 1944–53 There were relatively slight fluctuations until 1949, and thereafter a dramatic fall to about a ninth of the previous incidence—a fall which seems to be related to the consecutive decrease in the mean intervals between examinations Taken in conjunction with the fall in incidence of clinically disclosed disease, it seems probable that, if annual fluorography is maintained, tuberculosis following infection within the Royal Navy will be controlled and kept at a minimal level

How variable is the extent of inapparent tuberculosis over the world may be illustrated by quoting, the experience of a fluorography unit working in the Persian Gulf, with Arab employees who had been clinically examined previously An incidence of pulmonary tuberculosis of 22 per 1000 fluorographed was found This figure is the more remarkable because where racial resistance is low, as it is in Arabs, the proportion falling ill with tuberculosis (and so not fluorographed in this survey) will be relatively high With a diminishing incidence of disease in this country, on the other hand, mass radiography will prove more and more costly—where cost is measured by the yield of cases in relation to the money and time spent Increasingly strong arguments will therefore arise for the concentration of the procedure upon certain population groups—e g , the elderly—whose incidence of undisclosed disease is known to be high They will be justified only if iatrogenic neurosis does not then prove too serious an obstacle for what is, and I hope will remain, a voluntary examination in a civilian population Where everyone is examined, such an objection does not arise Mass radiography, and indeed all the other preventive measures we have discussed, if they are to be used successfully in a free society to preserve health, depend fundamentally upon public opinion about the disease in question Education, and less certainly propaganda, may influence this, but both are slow processes Health legislation has always been found ineffective if not backed by public sentiment, even in a disciplined fighting service such as the Army—as *Pringle* indicated as long ago as 1752 when he said

> "The prevention of disease cannot depend on the use of medicine or anything which the soldier shall have in his power to neglect, but upon such orders as he himself shall think not unreasonable and which he must necessarily obey"

In the last analysis, the prevention of tuberculosis, by those methods we know today as well as by those methods we may find tomorrow, depends on the will of the people

I am indebted to the Medical Director General for permission to publish statistics relating to the Royal Navy

SENIOR LECTURER IN CHILD HEALTH IN THE UNIVERSITY OF DURHAM

Hæmatogenous osteitis is still an important cause of crippling deformity, and a potential cause of death in the newborn This fact tends to be obscured by the surprising mildness of many of the cases (Dillehunt 1935, Cass 1940)

The recognition of two grades of severity (Greengard 1946) was an important step towards clearer understanding of this disease For this reason neonatal osteitis requires to be treated as a separate entity from the osteitis of older infants, which is almost invariably mild and has an excellent prognosis

Unfortunately no criterion other than personal impression has been suggested for distinguishing between the mild and the severe cases (Dennison 1955a), and we cannot suggest a better, because a precise clinical definition of severity appears unattainable and because the ultimate severity of certain cases can be so much influenced by the promptness with which effective treatment is started The difficulty of clinical assessment is illustrated by the fact that it is usually impossible to decide even how long the disease has already lasted when the patient is first seen

Any attempt to describe the clinical picture and treatment has to be set against this unsatisfactory background of extreme variability and lack of clear clinical definitions, but the attempt seems worth while because Dennison's (1955a) authoritative contribution leaves room for further discussion of the all-important questions of early diagnosis and treatment with antibiotics

Material

40 cases of neonatal osteitis have been treated by us at some stage (not necessarily the acute stage) of the disease in the past eight years 21 were classified as severe and 19 as mild A *Staphylococcus aureus* was recovered from the pus in 24 cases, a *Streptococcus hæmolyticus* in 5, a pneumococcus in 2, and an *Escherichia coli* in 1, no pus was available in the remaining 8 Of the 24 strains of *Staph aureus* 16 were resistant to penicillin in vitro, 7 were sensitive, and 1 was not tested (but the patient responded well to penicillin) All the strains of streptococcus and pneumococcus were sensitive to penicillin, and the *Esch coli* to streptomycin Where possible we relied on the bacteriologist's report of the in-vitro sensitivity when deciding which antibiotic was most suitable for each case, and we had no reason to regret any decision based on this information

Early Diagnosis

The natural history of the disease covers a remarkably wide range of severity The mildest cases show a strong tendency towards spontaneous recovery without complications of any kind, but the most severe cases are characterised by rapid dissemination through the blood stream, with formation of metastatic abscesses elsewhere in the skeleton or in vital organs, such as the lungs and the kidneys

It seems to us impossible to judge the potential severity of any case when it is first seen; what at first appears a mild infection may become really severe within a few days in the absence of effective treatment (see case 4, under "Failures"). We have therefore come to regard it as a matter of great urgency to make the correct diagnosis and to start effective treatment.

The rewards which can be won by successful application of this policy are illustrated by the 5 patients in this series in whom the upper end of the femur was involved. In 4 of them there was considerable delay—5, 8, 20, and 27 days—between the first recognisable signs of osteitis and the start of effective treatment. In all 4 the hip-joint was destroyed, and they were left with an absent, hypoplastic, or greatly distorted femoral head (as were the 3 patients in whom a hip-joint infection originated in the pelvis).

Case 13, however, was admitted to the Babies' Hospital for treatment of a large abscess in the left cervical and axillary groups of lymph glands. During his routine examination on admission he moved his left leg less than his right, and thickening and tenderness round the upper part of his left femur were detected (although his mother had not noticed anything abnormal). He was immediately started on treatment with intramuscular penicillin, at first 3 hourly and later 6 hourly, and after 11 days was sent home to continue with a single daily injection of procaine penicillin for a further 11 days.

The pus aspirated from the gland abscess grew a *Staph aureus* fully sensitive to penicillin. The femoral lesion required no local intervention, and the hip joint remained free from infection. The left leg was clinically normal on the 7th day of treatment and remained so thereafter.

The radiological changes were severe by 2 months from the start of treatment, with well marked patchy rarefaction in the femoral neck and slight raising of the periosteum over the upper two thirds of the shaft. By 3 months both femoral heads were visible in the radiographs, however, and by 9 months the left femoral head was as good as the right, and the shaft appeared to be completely healed.

The attainment of this objective—correct diagnosis and effective treatment as early as possible—depends on appropriate action being taken by one or more observers (mother, nurse, family doctor, and hospital) as soon as the first signs of disease appear. In our 40 cases the following were the first signs noted by one or other of these observers: swelling, with or without discoloration of the skin (14 cases), excessive irritability, often increased by handling (13 cases), relative immobility of a limb ("pseudoparalysis") (9 cases), and signs of severe general infection with or without fever (4 cases). The last of these signs was recorded only in severe cases, but the other three signs were noted as the first sign of disease in mild and severe cases with about equal frequency. In most cases two or more of these signs were already present when the patient reached hospital, and the cardinal sign of tenderness over the bone was clearly elicited.

The average delay between the appearance of the first sign and the start of effective treatment in the 21 severe cases was 8 days. In 5 of the 6 cases where the delay exceeded 10 days it was largely explained by the doctor's failure to make the correct diagnosis in the first instance: 3 had been treated as soft tissue infections, 1 as a severe generalised infection without specific localisation, and 1 had not been treated. In the 19 mild cases the average delay was a little more than 8 days; but in 3 of the 6 cases where it exceeded 10 days the greater part was due to the mother's failure to call the doctor sooner.

Consideration of the causes of any delay in arranging appropriate action, on the part of either the doctor or the nurse who first saw the cases in this series suggests that nearly all of it could have been avoided if the following points had been appreciated:

(1) Any tenderness or relative immobility of a limb during the first few weeks of life, with or without swelling of the overlying soft tissues, is more likely to be due to infection than to any other cause except trauma. Attention may often be drawn to the local signs by the fact that the baby cries excessively, especially when the affected part is handled—e.g., when the legs are handled during napkin changing. If the effects of birth trauma can be *confidently* excluded, the case should be regarded as one of infection until proved otherwise.

(2) The primary site of the infection is much more likely to be in bone than in the subcutaneous tissues. Although primary bloodborne abscesses of the subcutaneous tissues can, of course, occur in the newborn they are relatively very rare; in this series of 40 patients who, between them, had 70 known lesions of osteitis, only three primary abscesses of the subcutaneous tissues were detected, in 2 patients.

(3) The prognosis and possible complications of a bone infection in a young baby are so serious that the patient should be referred at once to a hospital where the necessary special types of clinical experience and laboratory facilities are available. The differential diagnosis from trauma, other forms of infection, and poliomyelitis (rare as it is in the newborn) may be very difficult or impossible on clinical grounds alone, as in the case of a baby who, born at home and cared for by a resident private nurse, developed a painful swelling over the lower end of the right femur at the age of 14 days and became irritable. The patient was admitted to the Babies' Hospital and started on treatment with penicillin until the routine radiograph (which should always be taken as soon as possible) showed a fracture. Within a few weeks further fractures occurred, and the diagnosis of osteogenesis imperfecta was established.

Surgical Treatment

Our policy as regards surgical treatment has been to try to remove pus, by aspiration through a short large-bore needle, in any case where there is appreciable swelling of the soft tissues overlying the lesion. In most such cases (including all the severe cases) pus has been obtained; but considerable perseverance, including the use of gentle expression of pus through the needle, may be necessary to achieve adequate emptying of the abscess. The aspiration is repeated as often as the local signs suggest that pus has reaccumulated. In case 4 (who weighed 8 lb.) 320 ml. of pus was aspirated from a single lesion during the baby's first 10 days in hospital. In cases where the joint is infected we inject either penicillin 50,000 units or streptomycin 50 mg. after aspirating the pus and washing out the joint cavity with isotonic saline solution. In 2 cases repeated removal of sequestra was necessary (cases 30 and 33 reported under "Failures").

No immobilisation was used in most of the cases. When the humerus was involved nursing was made easier by strapping the baby's forearm to his trunk. When either the knee or the ankle-joint was involved, a well-padded plaster splint was applied over the front of the limb to obtain the best possible support for the proximal part of the splint. Where the hip-joint was involved, however, we found no really satisfactory method of immobilisation in the acute stage. After finding plaster casts of various kinds quite unpractical, we experimented with a modified form of gallows suspension using weight and pulley traction and tried to hold the hips in moderate abduction and flexion. We cannot yet say anything about the long-term results of this method, which can be successfully applied by the average mother at home after the need for penicillin injections and aspirations is over; but we doubt if any method can do much to prevent, or even *modify*, permanent damage to the joint in cases where the hip is already severely infected when treatment is started.

After the infection is controlled the extent to which satisfactory remodelling of the affected bone can take place in some cases has to be seen to be believed; but, in our experience, no such satisfactory recovery takes place in cases where the hip joint has been seriously damaged by the initial infection. In 5 of our 7 cases of this kind we gave prolonged treatment on conservative lines as for congenital dislocation of the hip, keeping the patients in plaster for 3, 7, 10 11, and 12 months The results did not justify the effort, and we now doubt if the attempt to prevent these deformities by these means is really in the patients' best interests

Antibiotic Treatment

The importance of early diagnosis and immediate treatment with an effective antibiotic has already been emphasised The selection of the best antibiotic with which to start treatment, before the results of any bacteriological tests are available, has been made much more difficult by the emergence of a high proportion of penicillin-resistant strains of *Staph aureus* during the past few years, at least in babies born in hospital We still regard penicillin as the drug of choice and start treatment with it in a dosage of 25,000–50,000 units intramuscularly every 3 hours, reducing to 6 hourly administration when it is clear that a good clinical response is being obtained, and finally changing to oral administration in some cases to enable the mother to take her baby home for the completion of his treatment

It would be foolish to rely on penicillin alone until the sensitivity of the organism is known ; In selecting the most suitable partner to penicillin for this purpose of initiating treatment, when the need for such a partner was first appreciated, we rejected streptomycin largely because we expected that the emergence or resistance to streptomycin would soon overtake, in frequency, the resistance to penicillin which we had observed, but we were wrong Only two of the twenty three strains of *Staph aureus* recovered from our cases and appropriately tested were resistant to streptomycin in vitro

This fact is causing us seriously to reconsider our policy, which has been to use aureomycin (chlortetracycline) routinely as the partner to penicillin until the results of sensitivity tests are available (or throughout the course of treatment if no organism is available for testing) Unfortunately there are practical difficulties about using streptomycin in certain cases for instance, a suitable injection site may not be available for a drug which causes considerable local reactions, as in case 4, where the left leg was involved in the osteitis and the right thigh was occupied by a chronic ulcer resulting from a nikethamide injection given in the Maternity Hospital We are therefore at present exploring the possibility that a tetracycline may be effective if given in larger than standard dosage at the start of treatment, and this point is discussed in relation to the clinical history of case 15, reported under "Failures" In the end it may seem wiser to start with a combination of penicillin and streptomycin, as suggested by Dennison (1955a), and to rely on a tetracycline only for continuation of treatment in those cases where the organism is resistant to penicillin

The proper duration of the antibiotic treatment is the one subject of real controversy (Dennison 1955a and b, Neligan 1955) Far from being unduly optimistic about the control of the ' unconquered staphylococcus " in neonatal osteitis by modern methods of treatment, we believe that the extreme seriousness of the disease, and of its potential local and systemic complications, demands that we give the natural processes of resistance and repair the greatest possible assistance, in the shape of effective antibiotics and that we continue to give this assistance until uninterrupted recovery is assured by complete elimination of the infection In severe cases where the start of effective treatment has been delayed, with the result that the pathological changes in the bone are already very extensive it seems to us advisable to prolong the antibiotic treatment correspondingly for many weeks or months, until revascularisation and absorption are complete In the 18 severe cases whose initial course of antibiotic treatment was given by us the average length of this course was 41 days (range 21–116 days) and with increasing experience we have tended to increase the length of the course

But we do not base our policy solely on theoretical arguments , nor is our strong opposition to the advice of Dennison (1955a), that "whichever antibiotic is used treatment with it should be discontinued as soon as the blood infection appears to be controlled," explained only by our inability to accept the theoretical arguments which he puts forward in its support We prefer to depend on the difference between the subsequent courses of two groups of cases whose initial antibiotic treatment differed much in duration

Of our 40 patients 1 died (case 2, under "Failures") and 1 was not adequately followed up , 31 of the remainder had an initial course of a suitable antibiotic lasting 3 weeks or more (average 34 days, range 19–116 days) 25 of these patients (12 severe and 13 mild) appear to have recovered completely from the infection after this initial course, judged by satisfactory clinical and radiological progress thereafter 6 had one or more recurrences of infection and are discussed under "Failures" (cases 4, 19, 21, 25, 30, and 33) These results give little enough cause for undue optimism (particularly since, as stated, they take no account of the fact that 10 of the patients were left with one or more abnormal joints), but at least they compare very favourably with the results in the remaining 7 cases, the length of whose initial course of treatment with an antibiotic to which their organism was sensitive was quite inadequate by the standards which we have adopted

The initial course of antibiotic treatment in these 7 cases averaged 7 days (range 4–13 days) 1 case showed no recurrence of infection after a week's treatment with chloramphenicol for a mild osteitis of the maxilla, from which an infected tooth-bud was removed on the same day as the antibiotic was started, 14 days after the first sign of the disease had appeared The remaining 6 patients had, between them, twelve recurrences of infection after twelve short courses of antibiotic treatment, administered either at home or in other hospitals, for what were thought to be infections of the soft tissues or of the blood The treatment was stopped in each case when the clinical response was regarded as satisfactory The average delay in starting treatment was less than 3 days In all 6 cases (3 mild and 3 severe) the organism causing the osteitis was sensitive to the antibiotic used for the initial course, and all of them eventually responded completely to a more prolonged course of treatment with the same antibiotic (average duration 43 days, range 21–58 days) In 2 of them pus was aspirated once at the start of this final course of treatment, but the others required no additional measures of any kind In 1 of these 6 cases the story was not quite so straightforward as this summary suggests, and it is reported in greater detail under "Failures" (case 15)

These results (see table) provide clear cut evidence in favour of using a suitable antibiotic for at least 3 weeks, and much longer if necessary, from the time when the patient is first admitted to hospital The same conclusions about the need for prolonged antibiotic treatment

EFFECT OF DURATION OF INITIAL COURSE OF APPROPRIATE ANTIBIOTIC

	Adequate duration *		Inadequate duration	
	Severe	Mild	Severe	Mild
Average duration (days)	43	26	8	7
No of cases	17	14	3	4
No with recurrences	4	1	3	3

* Adequate is defined as lasting for at least 3 weeks

had been reached by Disney et al (1956) as regards staphylococcal pneumonia in young babies But we are much concerned with trying to understand the reason for the failures which can still occur, and they are briefly reported and discussed below

Failures

Under this heading are discussed the 1 death, the 6 patients who had one or more recurrences of infection after an initial course of antibiotic treatment lasting 3 weeks or more, and case 15 mentioned above

Case 2 (severe) died at the age of 27 days, after 11 days' treatment with chloramphenicol He had become ill, at the age of 11 days, in a maternity hospital and was at first treated with penicillin After 5 days the clinical response had been most unsatisfactory, and the organism recovered from the pus aspirated from his right shoulder was resistant to penicillin but sensitive to chloramphenicol in vitro (this finding was repeatedly confirmed in pus from other sites obtained later) When he was transferred to the Babies' Hospital at the age of 16 days he already had overt lesions of osteitis in both humeri, both hands, and the right mandible His response to chloramphenicol was never encouraging, blood culture still being positive on the 6th day of treatment, and he died with gross signs of heart failure Necropsy revealed, in addition to the bony lesions, well developed abscesses in the lungs with several small encysted empyemas (whose presence had been suspected some days before death but had not been confirmed on aspiration)

Comment—We attribute this baby's death, and the failure of treatment with chloramphenicol, to our not draining collections of pus within the chest when treatment was started

Case 4 (severe) developed an abscess of the right thigh at the site of an injection of nikethamide given at birth, and osteitis of the middle phalanx of a finger was diagnosed at the age of 12 days She was started on treatment with penicillin at once, but 4 days later she was sent home from the Maternity Hospital without the visiting pædiatrician's knowledge

At the age of 20 days she developed an abscess over the upper part of the left tibia, which the family doctor treated with penicillin for the next 6 days, he also incised the abscess

By the age of 31 days, when she was first admitted to the Babies' Hospital, she was seriously ill, with further lesions over the left clavicle and over the left ilium and hip joint 340 c cm of pus was aspirated from her lesions during the next 10 days

Three days after admission the *Staph aureus* cultured from her pus was reported as being resistant to penicillin but sensitive to chloramphenicol She was treated with chloramphenicol for the next 21 days, when we stopped it because of the potential toxic effects There was no part of her body into which we felt we could inject streptomycin, and no other antibiotics were available at that time

6 weeks later she had a recurrence of infection over the clavicle, a year later she had a recurrence over the left tibia, at the age of 4 years she had a further minor recurrence, and at the age of 5 years she had a recurrence over the left ilium, which has not completely healed yet a year later

Her left hip joint is dislocated and the femoral head very abnormal, in spite of 10 months' treatment in plaster during the first year of life as for congenital dislocation of the hip

Comment—Although this case is included as a failure of prolonged treatment, we did not consider the 21-day course of chloramphenicol really adequate in view of the length of her history, but we can only speculate about the likely result of a more prolonged course of treatment given at that stage There is little doubt in our minds, however, that an adequate course of an effective antibiotic, given when she had only a mild osteitis of one phalanx, would have produced a very different result

Case 21 (severe) was admitted to hospital 2 days after developing signs of osteitis in his right humerus Penicillin was stopped 3 days after admission when his *Staph aureus* was reported to be resistant to penicillin but sensitive to aureomycin He was treated with aureomycin for 43 days after admission, and three aspirations during the first 10 days in hospital produced 9 c cm of pus He had a recurrence at the age of 8 months, and another mild one at the age of 2 years

Comment—In this case the duration of the initial antibiotic treatment was regarded as adequate, but the radiological changes which developed, with wide separation of the periosteum from the cortex of the shaft suggested that the aspiration of the subperiosteal abscess had been inadequate and ineffective

Case 19 (severe) developed multiple lesions of acute osteitis in a maternity hospital at the age of 8 days, with involvement of the left foot, left index finger, left mandible, and right lower femur He was started on treatment with chloramphenicol at once, and after 3 weeks aureomycin was substituted and was continued until the total course of antibiotic treatment was 53 days A few days after the onset crepitus was detected over the right lower femur, and radiographs subsequently showed that the lower femoral epiphysis had been displaced about an inch backwards, leaving the lower third of the shaft protruding through the anterior wall of its periosteal sheath

Various methods of immobilisation were used to try to prevent further displacement during the next few weeks, and the bone has shown remarkable powers of reconstruction and longitudinal growth The boy walked unsupported at the age of 16 months and since then has led a normal active life But at the age of 8 months he had a recurrence over the lower end of the femur, with spontaneous discharge of a flake sequestrum measuring $^1/_4 \times {^1/_{16}}$ inch, and at the age of $3^1/_2$ years he had a superficial swelling in the scar, from which a bead of sterile pus was aspirated

Comment—The only lesion which caused any further trouble in this case was the one in which there must, initially, have been extensive interference with the blood-supply of the affected bone This fact suggests that it would have been wiser, and possibly more effective, to continue the initial course of treatment for longer than 53 days

Cases 30 and 33 (both severe) are reported together because they have many features in common In case 30 there was a delay of 14 days after the first sign of osteitis of the mandible before admission to hospital, and in case 33 the delay was 19 days after the first signs of osteitis of the right parietal bone of the skull Both were draining pus freely, in large quantities, on admission In both cases the *Staph aureus* was resistant to penicillin, and aureomycin was used for initial courses of 55 days and 116 days respectively In both cases sequestra had to be removed and further prolonged courses of aureomycin given Now, about $1^1/_2$ years after the onset, neither case can yet be regarded as completely healed, but the most striking feature of both patients is their magnificent physique and healthy appearance
